THE CARE AND TREATMENT OF CEREBRAL PALSIES

WINTHROP MORGAN PHELPS, M.D.
BALTIMORE

The care of cerebral spastic paralysis is a rather general problem in which the orthopedic aspect is the biggest single factor, but orthopedic measures alone will not in many instances accomplish the desired results. The problem deals with a deviation from the normal which has existed since birth in most instances. This particular factor differentiates the paralysis from acquired conditions. When one considers the motor side alone, it is easy to see that primary action patterns such as alternation of the legs and function of the reach and grasp may not be automatically developed. Likewise, the ability to suck and to swallow and the primitive throat and tongue motor patterns, from which speech originates, may not have been developed. The relationship of these defects to the total picture of the intelligent person is the problem. All teachers are insistent on a thorough knowledge of fundamentals in any teaching problem. In the case of spastic paralysis the absence of physical fundamentals makes subsequent teaching unsuccessful unless thought and care are given to all the fundamentals which may be lacking in the original development.

It is necessary to determine what must be the aim of treatment. A broad statement is that the object is to make the child fit the groove of normal humanity. "The groove" is a vague concept of the type of behavior which is expected of the average person. Physically he walks without a limp, he speaks in a certain way and the way he uses his arms is dependent on the apparatus with which he is surrounded. He laughs only in moderation; he does not cry publicly. There are definite racial and national behavior habits. The fiery Italian, the stolid Indian and others show apparently national characteristics, and the behavior of the individuals of each race is normal for them but not for other races or nationalities. Even differences in methods of walking can be demonstrated, and the excessive use of the arms in gestures is familiar to all. The greatest national or racial difference is in speech. Some languages lack entirely the sounds which are common in others. A foreigner speaks with an accent which is a definite handicap when he is transplanted to a nation with another language. When a member of any race or nation is transplanted he seldom automatically fits the groove.

DETERMINATION OF MENTAL DEFICIENCY

The person who is handicapped from birth is further from the groove of his particular race or nation than

is any one else. The problem is a many-sided one which no one person is trained to solve, because the various points of view cannot be satisfactorily attained by one person. The gait of a child and his emotional behavior are apparently not very closely related, but in making him a normal human being one is as important as the other. The child must be measured against the theoretic normal from all points of view. The commonest measurement is the determination of the mental age by the Binet scale or some similar system. The mental age, however, is far from the only age which must be measured in the child handicapped from birth, as it is impossible to determine exactly what limitations the complicated handicap may impose. He must also be measured physically, so that the percentage of the ability to move at a given age as compared to that of the normal child will be known. He should also be measured from the point of view of his social competence. Doll and his co-workers in Vineland, N. J., have evolved a scale of social competence for measuring the social age, and this is important in connection with the child with spastic paralysis.

Because the centers controlling laughter, crying and the other motor pictures accompanying emotion may be affected, the child's emotional age should be determined so far as possible. Definite attention must be given also to his interests and aptitude, since the handicapped child is likely to develop unevenly because of inability to enter into the normal activities of other children of his own age.

It is only after all these measurements have been made that it can be determined whether definite mental deficiency is a part of the picture.

The brain is such a complicated mechanism that it is impossible to imagine two injuries which would be alike. The division in general of motor injuries to the pyramidal system and motor injuries to the extrapyramidal system is very important as a factor in determining where the lesion is in the brain. The location of the lesion should have some bearing on the probability or the lack of probability of mental deficiency. If it can be determined, as it sometimes can, that the injury is at the base of the brain and that the cortex of the brain is not involved in any way, it is difficult to explain true mental deficiency as a result of the injury. A differentiation must, of course, be made between true mental deficiency and retardation on the basis of the handicap.

Often the true underlying situation can be determined only by a test of teaching; if the child can be made to progress and learn at the rate of a year per year, then obviously true mental deficiency is not present; instead, the ability to learn by the usual methods is blocked by some part of the handicap, and special teaching methods are necessary.

CEREBRAL PALSY

The distribution and the number of persons with cerebral palsy throughout the United States are not clearly known. A few surveys have shown that the number is greater than the number of persons with infantile paralysis, while other surveys have shown that it is somewhat less. Apparently the conditions are almost equally frequent. Many of the subjects are in institutions for the feeble-minded; many others are homebound, and a certain number, which appears increasingly large, are being taken care of in the public schools. Still another group may be found in the private schools for defective children, the membership of which is often composed largely of such children.

The percentage of these children who are truly feeble-minded is not known, but the percentage who are mentally normal but suffering from retardation due to the handicap is apparently greater than the actual number of feeble-minded. As methods of teaching are developed, the number of supposedly feeble-minded children is decreased still further.

The majority of the children are suffering either from congenital malformation or maldevelopment of the central nervous system or else from an injury that occurred at about the time of birth. Actual obstetric injury is found to play a comparatively small part. By obstetric injury is meant damage to the child due to poor handling of the obstetric problem. Two general types of injury may cause cerebral palsy: first, damage to the cortex of the brain, which most frequently results from misplaced or too tightly placed forceps, and, secondly, injury to the base of the brain resulting in a hemorrhage into the basal nuclei from a tear of the tentorium and the vein of Galen, as a result of too strong traction and stretching of the neck, which has been demonstrated by Crothers. The first type of injury, the cortical type, produces definite spasticity, while the second type of injury, the basilar type, produces athetosis, tremor or incoordination of some sort.

SPASTICITY AND ATHETOSIS

With a congenital defect, as compared to an injury received at birth, it has been shown that there may be a congenital anomaly or deficiency in the cortical or pyramidal system, resulting in spasticity, or a definite abnormality or absence of part of the basal nuclear mechanism, resulting in athetosis, tremor or incoordination.

The third chief cause of cerebral palsy is the damage produced by encephalitis, and in some postencephalitic patients the damage is essentially that which produces spasticity and in others essentially that which produces athetosis. One is therefore dealing with a triple cause, namely, congenital malformation, injury received at birth and postencephalitic manifestations. One is also dealing with two resulting conditions: first, spasticity and, second, athetosis or involuntary motion. It was formerly supposed that the combination of these two conditions is frequent, but on careful study it was found that, although the combination does occur, it is comparatively rare. A possible mechanism of its occurrence, for example, is extremely rapid birth of a premature child. The walls of the blood vessels are perhaps not as strongly developed as they would be if the child were born at term, and the sudden release from the greatly increased pressure within the uterus to the comparatively low pressure of the air outside can produce petechial or multiple hemorrhages in the brain which result in a condition similar to the "bends," or

caisson disease, and in diffuse damage to the brain, with perhaps a mixture of spasticity and athetosis, depending on the distribution of the hemorrhages. It is necessary to make a clear differentiation between spasticity and athetosis, however, because the treatment of the two conditions is very different. If one thinks of spasticity as stiffness of muscles and athetosis as involuntary motion, the greatest difference can be seen between them. However, the results produced when the child attempts to move are sometimes so confusing that the difference is indistinguishable at first sight, as the spastic child in attempting to move brings about the stretch reflex, which causes contraction of other muscles involuntarily, but secondarily to the attempted motion, and results in incoordination. The athetoid child, on the other hand, has involuntary motion before he attempts to make a voluntary movement and attempts to stiffen the muscles or contract them strongly in order to control this involuntary motion. The effect looks like spasticity and also results in incoordination. It is sometimes difficult to determine which condition is being dealt with in less than several hours of study of a given patient.

The neurologic examination, of course, should be entirely different for the two conditions. In the first place, if a pyramidal condition, or true spasticity, is present there should be hyperactive knee and ankle jerks, a positive Babinski sign, occasionally ankle clonus, diminished or absent cremasteric and abdominal reflexes and hyperactive biceps, triceps and periosteal reflexes. These changes are characteristic of damage to the pyramidal system and should be found. In the case of athetosis, on the other hand, or extrapyramidal disturbance of any kind, the reflexes should be essentially normal. That is, the knee jerks and the ankle jerks should be normal. A Babinski sign may be present. The reason for this is not clearly understood at the present time, although there are many theories. The cremasteric and abdominal reflexes and the arm reflexes should be normal.

Great care must be taken to determine that these tendon reflexes are really normal, however, as it is easy to mistake a reflex that is being reinforced automatically by involuntary motion for a true hyperactive reflex. It is only by eliciting the reflexes over and over and finding that they are normal part of the time that a true diagnosis of extrapyramidal dystonia can be made.

The necessity for differentiating these two conditions has been emphasized because not only is treatment of the two conditions different but the general characteristics of the spastic subject and of the athetoid subject differ widely. The patients respond to situations in a different manner, and their behavior is different under similar circumstances.

When there is speech involvement, the type of speech defect is entirely different. With spasticity the defect is rather uniform, and the type of speech utilized by truly spastic subjects can be learned easily by those working with them to any extent. It is due, of course, to definite spasticity in some part of the speech mechanism, and the result is speech that is defective but in definite ways. In the athetoid patient, in whom involuntary motion is the primary difficulty, the speech is upset by the involuntary motion of the tongue, for example; and as the involuntary motions never coincide with the voluntary ones made on the patient's attempt to speak, the words never come out distorted.

in the same way but on repetition are spoken a different way each time. No amount of attempting to say the word over will result in improvement, as the word will be distorted in a different direction on each trial and the patient will finally give up the attempt entirely. On the other hand, repetition and training of this sort in cases of spasticity produces clearly defined improvement.

This point is brought out for the purpose of showing one of the definite differences between the two types. It can be said that throughout the entire treatment repetitive methods are of definite use for spasticity but are of no avail for athetosis, as with the latter attempts to carry out definite repeated activities in speech or in the use of the arms or legs are doomed to failure. This difficulty is carried over into the mental and general life, and repetitive methods have been found to be generally unsuccessful in all lines in the teaching of athetoid children. It is important that the differences in behavior and in methods of training be known by all who come in contact with such children not only in the orthopedic field but in all fields in which attempts are being made to improve them. Studies are being made at the present time on the differences in the behavior of the athetoid and of the spastic child which should be very enlightening when completed.

PLAN OF TRAINING

It can be seen that the training of such children is a general problem and involves the orthopedic, psychologic, speech and educational fields. The activities must be so interrelated that the therapist in each field knows clearly what is being carried out in the other fields.

In the educational field, in the teaching of normal children a definite course has been set up. This begins with fundamentals, and the various branches are brought in at certain ages. Thus "the three R's" are taught in the first grade, whereas such things as economics, languages and political science are brought in at entirely different points in the education. The times at which these subjects should be taught have been to some extent decided on. In the case of the child who has been crippled or handicapped in speech and action since birth, a similar regimen must be set up to care for the physical and motor side and to parallel the mental educational system.

Obviously, fundamentals must be stressed first, and in this instance fundamentals represent primary motor activities. No reliance must be placed on what are generally considered automatic instinctive activities. The young animal is able to walk if not on the day of birth at least within a few days, because of the automatic application of alternation in the legs in muscular contraction. This alternation can be seen in the human being in the kicking motion which babies normally carry out very early. However, if a part of the motor mechanism which controls alternation is interfered with, alternation will have to be taught as a voluntary function and trained into the habitual level before any attempt at alternate progression of the legs can be made.

In the spastic child this difficulty is often met, but it is interesting to see that even with the spastic baby alternation can be taught and trained into a habit. In the athetoid child, on the other hand, the primary ability to move is undisturbed, since the damage does not lie in the pyramidal or voluntary motor system, but the activities are hampered by the superimposition of invol-

untary motion, which steers the voluntary attempts in the wrong directions. Thus even the fundamentals which must be taught to the spastic and to the athetoid child are entirely different. If a normal person attempts to write on a piece of paper in a rapidly moving automobile on a rough road, his instinctive reaction is to steady himself by tensing the arm and body. This tension however will result only in worse writing, as all the jolts produced by the automobile are thus much more forcefully transmitted to the hand. If, however, the person attempts to loosen up completely and relax, all the joints act as shock absorbers and the writing is much improved.

The athetoid child reacts to his involuntary motion by voluntary tension, and after a number of years the tension habits become so fixed that he cannot make any motion without bringing in extreme stiffness. His habits must be unlearned in order to bring about a diminution of the athetosis. Athetosis disappears during sleep, and the amplitude of the involuntary motions decreases greatly with relaxation and increases with increased tension. Through the teaching of extreme relaxation the amplitude of the involuntary motions associated with athetosis can, in many cases, be so reduced as to be almost negligible. It is possible to teach relaxation by special methods to very young children and even to babies, and once the subject has realized the advantages of being relaxed he can substitute a habit of relaxation for one of tension, and improvement can go on more rapidly. It is therefore not necessary, for example, to teach a truly athetoid child alternation exercises of the legs, since the mechanism for alternating motion is essentially pyramidal and is not disturbed but only blocked by the athetosis. Repetition of alternate motions of the legs passively, as in bicycling, is of use in the case of spasticity and in itself will bring about habitual alternation. In the case of athetosis, however, no amount of repetition will do any good unless attention is first given to relaxation, and when relaxation has been accomplished the alternation will be normally present.

Another phase of the problem which must be considered before a treatment unit is set up is the distribution of the involvement in the individual case. Is the child most in need of being taught to walk or are the problems of speech or of use of the arms more important? A great many children are seen who have been the rounds of many physicians and on whom a large amount of the time has been spent on operations and treatment for the legs although the arms and the speech are practically useless. Of course the problem is relatively simple when the child has spasticity or athetosis involving the legs alone. The attention of course should then be centered on teaching him to walk if possible and on improving the use of the legs. However, when the legs and likewise the arms are useless, the question of future walking is much dependent on the development first of the proper use of the arms. The balance sense is usually badly disturbed, and it is necessary for the child to use a crutch or a wheelchair for a period before attempting free walking with the legs and obviously if the arms are useless they cannot help in balance, and the use of crutches is out of the question. It is important to have a clear realization that this stage must be carried through before walking can really be accomplished. This fact is too often forgotten. In the case of a severely handicapped child who has no use of the arms or legs and little or no speech, it would seem that the most desirable improvement to begin with would

be to obtain speech, so that communication could be carried on more freely and normally between the patient and those around him.

The attitude of the family is often interesting. In such cases as the one just described I have seen the members of the family insist that what they wanted was to have the child taught to walk, while it was at the same time necessary for them to do the dressing and feeding and to interpret the child's poorly developed sign language for communication.

The distribution of the handicap in the patient is important from another standpoint also. It is necessary to consider the education of the diplegic child with normal arms from an entirely different point of view from that of the hemiplegic child who has only one bad leg but also one useless arm. There are many occupations for the person whose arms are normal which can be carried out while he is sitting in a chair. It is necessary only to make him independent, so that he can go to his place of occupation. But when one arm is involved the problem is much more complicated. It would seem important to carry the education of the hemiplegic patient far beyond that of the diplegic patient, as the gainful activities are so much more limited for the latter than for the former.

In determining the proper regimen and method of treatment, therefore, one must determine first what the various age levels are. That is to say, the mental level, the level of physical ability, the emotional level and the level of social competence. The distribution of the handicap must then be considered and a decision made as to whether the work is to be concentrated on walking, use of arms, speech or a combination of these functions. The degree of the handicap should then be roughly determined. It is customary to classify it simply as severe, moderate or mild. In the case of the child who is seen during babyhood, that is to say, in the first year of life, the three particular fields in which treatment should be carried out are, first, development of simple motor coordination; second, behavior control, and, third, the simplest control of psychologic reactions to situations.

TIMING

A great deal can be gained by starting treatment in these fields very early. The sooner the child is able to find out that a special regimen is necessary in order to make his body work for him, the less unteaching of bad habits of action will have to be utilized. During the preschool period, that is, between the ages of 2 and 5 years, the speech work should be begun. It is useless of course to attempt to teach speech to babies under 1 year old. They learn gross motor coordination involving large joints, such as the hips, the shoulders and probably the elbows and knees, comparatively easily, but little should be done at this stage with regard to the fine coordinations, which are not normally developed in the child until the primary school age has been reached. In the preschool child, behavior is very important. It is necessary that he be much more responsive to disciplinary measures than the normal child, as the effort and the necessary obedience to make him carry out the corrective measures is important. It is during this age that walking should be started if it is to be attempted.

The teaching of these functions is begun at these ages because there is apparently an optimal age for the different activities. In other words, it has been seen that, if a child reaches the age of 5 or 6 before he is taught to speak, the attempt to teach him to speak is

much more difficult than if it is started during the period when he would normally learn to speak. This of course applies not to the child who is mentally retarded but to the child in whom the lack of speech is entirely due to the handicap.

The situation with regard to walking is the same. The normal child learns to walk before the age of 2. It is advisable, therefore, whenever possible to try to bring about walking during this period, as it will be much more easily accomplished. The reason for the greater difficulty in accomplishment of walking by an older child is obvious, as, when the body becomes larger and the child taller, the falls which the child takes when attempting to walk are much more painful and he is more likely to be hurt; but the optimal period is apparently also a factor in this particular activity.

When the child has reached the primary school age the motor reeducation should parallel the type of education which he is receiving at school. In other words, the finer motions of the hands and feet should be developed and the finer coordinated sounds of speech should be worked on particularly. It is necessary at this age to give considerable time to the question of behavior and psychologic adjustment to other children. Previous to this age the child is happy playing essentially by himself, but when he reaches school age group play becomes a more important factor. It is well to develop this if possible, as the handicap in many instances tends to work against it.

As the child becomes older the various activities become more skilled in type. For example, the child at the early primary school age spends a great deal of time playing games such as hide and seek and tag, which require little or no skill. After two or three years he attempts to roller skate or to skip rope, and a gross type of skill is developed. It is necessary to parallel this type of skill in the handicapped child who has reached that age. The idea of the optimal time for different types of activity should carry through the entire training period. It can easily be seen that types of skilled motion which are not learned by the normal child at a given age should not be taught the handicapped child before he has reached the age when he should acquire these skills naturally.

The actual method of treatment, as I have said before, differs markedly for the spastic and for the athetoid child. In the case of the spastic child the fundamental principle is that the spastic muscle contracts maximally to any stimulus applied to it. The most commonly applied stimulus is the stretch reflex. This is brought about by the voluntary contraction of the antagonist of the spastic muscle. An attempt to extend the arm in the case of a spastic flexor would result in an immediate contracture of the flexor, which would block the motion.

An examination of the muscles should be done in each instance to determine the distribution of the spastic muscles. It will be found that in each spastic extremity there is a spotty or unrelated group of muscles which show the stretch reflex. These can be charted as the spastic muscles. Another group of muscles will show normal contractility, and when an attempt is made to move the muscles passively against their direction of contraction no stretch reflex will be found. These muscles can be charted as normal. A third group of muscles will be found in which the voluntary ability to contract is entirely lacking. These muscles can be charted as flaccid muscles, although this particular type of flaccidity is different from that of the usual lower

motor neuron paralysis. (That there is such a thing as cerebral flaccidity has been shown by the work of Fulton and others, in the studies of the cortex of the chimpanzee.) The muscles then are grouped in antagonistic pairs, and it must be determined whether two spastic muscles are acting against each other, a spastic against a normal muscle, a spastic against a flaccid muscle or a normal against a spastic muscle.

The flaccid muscles must be treated in much the same way as the flaccid muscles of infantile paralysis are treated. That is to say, they must be protected from being overstretched and must be massaged to increase their tone. It has been found that, by forceful resisted contraction of some other muscles in the body, the flaccid muscles may frequently be brought into an involuntary, or automatic, contraction. This can be utilized as a stimulus for developing power in these muscles, and in many instances the patient can be taught to utilize this confusion to bring about a useful contraction in the apparently flaccid muscle. The normal group of muscles, of course, does not need any treatment whatever unless contracture has resulted from flaccidity of antagonists or from gravity.

SURGICAL PROCEDURES

The spastic group must be treated to reduce the spasticity by either gradual voluntary exercises or surgical intervention in the form of partial neurectomy. Neurectomy must be carried out with great care with regard to the degree of weakening to be accomplished. The deciding factors in the procedure are the state of the antagonists and the degree of spasticity in the muscle which is being operated on. For example, if a spastic muscle is pulling against a cerebral flaccid muscle, the degree of neurectomy will have to be more nearly complete than if this muscle were working against a normal muscle. The determination is made by the amount of power in the antagonist, and an attempt is made to balance the power as nearly as possible.

Other surgical procedures, such as lengthening of a tendon, are to be considered at times. Lengthening of a tendon produces a definite weakening of the power of the muscle. Actual tenotomy of a muscle or a tendon should rarely be done, as this leaves no power whatever in the muscle and it cannot work reciprocally against any antagonist. When three or four muscles perform the same function, such as adduction of the legs, tenotomy of some of the adductors will produce a weakening which will result in a balance of power if the abductors seem to be weak. Some patients have been seen, however, in whom complete adductor tenotomies have been done and in whom there is complete flaccidity in the abductors. Their ability to stand is entirely lost by the operative procedure.

Fusion of the joint and operation to block the joint are sometimes used but should be worked out with great care, as the pull of a spastic muscle against a blocked joint will eventually modify the block to such an extent that it might as well never have been done. More recently the technic of transplantation of muscles in the spastic extremity has been developed. Transplantation of spastic muscle is somewhat different from transplantation of muscle in the case of poliomyelitis, as the operative procedure itself so increases the irritability of the muscle postoperatively that unless it is very firmly transplanted the tendency for it to pull loose is great. There is probably a great future in this field in the treatment of true spastic paralysis. For example, the

transplantation of the tensor fasciae femoris laterally from its point of origin on the pelvis to the vastus lateralis has in my hands been satisfactory in counteracting the tendency to internal rotation so commonly seen in spastic legs. The muscle loses, by this procedure, its function of internal rotation but acts as a tensor of the vastus lateralis and thus aids to some extent in the ease with which extension of the knee is accomplished. This particular procedure I have now done four or five times and have found great improvement, but it should be done only after a careful evaluation of the power in the external rotators. Of course there is no limit to the possibilities in transplantation of muscle both in the arms and in the legs, and the operation, combined with partial neurectomy or other balancing procedure, can accomplish considerable improvement surgically. However, surgical intervention is really only a step in the treatment of the spastic patient. It should never be considered that he can be cured by surgical measures alone.

For the athetoid patient, on the other hand, little indeed can be accomplished by surgical treatment. Athetosis is not always fixed, and if an athetoid muscle is cut or eliminated by neurectomy or other procedure it is common to find the athetosis jumping to muscles which have not been previously affected by it. This is not always true but is true in so large a percentage of the cases that surgical procedures on athetoid muscles have at the present time been given up.

The basic principle in the treatment of athetosis is relaxation. As has been said before, athetosis disappears in sleep, and the more nearly an athetoid patient can be relaxed the less will be the amplitude of swing of the involuntary contractions in the muscles. Reeducation by teaching voluntary motion from the relaxed position is then utilized, and it produces great improvement. Even in cases of moderate athetosis, gradual elimination of the athetosis has been seen to such an extent that the only remnants of it were somewhat feeble contractions in certain muscles which do not actually bring about motion in the joints. Of course the problem is much greater when the athetosis is distal than when it is proximal.

For severe athetosis the only procedure at present known which is of any help except to induce relaxation is the operative procedure described by Putnam, section of the lateral columns of the cord. This eliminates a large part of the athetosis from the extremities, but there is considerable risk in the operation and cases should be selected with great care before a decision is made with regard to the use of the procedure.

NATURE OF THE PROBLEM

The general care, therefore, of the spastic and of the athetoid patient and of the patient with any other type of cerebral palsy is rather complicated. There must be a program correlated by the orthopedist, the pediatrician, the neurologist, the physical therapist and the speech expert for the motor side and by teachers accustomed to handling the problems of the handicapped on the educational side, and psychologic aid is necessary in adjusting these children and their behavior to the world at large. Physical therapy in the primary stages of the condition should be followed by occupational therapy when the primary motions can be performed and grouped. This should give way to vocational training when the patient is old enough to determine the line in which he is to be trained. The

program constitutes an effort to parallel the mental education of the normal child with a program for physical reeducation which for the normal child is to a great extent automatic.

It is unfortunate that children cannot be born mentally with the equivalent of a high school education. A parallel may be drawn that normal children are born with the equivalent of a physical high school education. It is not considered surprising that it is necessary to spend twelve years giving a child a mental education equivalent to that of a high school graduate, and the point of view toward the cerebral palsies should be that it is necessary to parallel this with physical education over a long period in order to bring in the abilities as they arise and train them as they are developed.

3038 St. Paul Street.

POLIOMYELITIS VIRUS IN HUMAN STOOLS

JAMES D. TRASK, M.D.

A. J. VIGNEC, M.D.

AND

JOHN R. PAUL, M.D.

NEW HAVEN, CONN.

More than twenty-five years ago Kling, Pettersson and Wernstedt¹ in Sweden were successful in isolating the virus of poliomyelitis from the human intestinal tract. They found it in several active cases of the disease and in convalescence. This result was soon repeated in a single fatal case by Kling and Levaditi,² and in this country another single instance of its recovery during convalescence was described by Sawyer³ in 1915.

During subsequent years no one seems to have been able to repeat this work until 1937, when Harmon⁴ made brief mention of five successful attempts in which the virus was obtained from the rectal washings of four patients. Kramer⁵ has stated that he also has succeeded with similar material.

The present report records our experiences in testing material from the intestinal tract and nasopharynx during a small epidemic of poliomyelitis which occurred in 1937. In it we describe (a) three cases of mild abortive poliomyelitis in each of which the virus was recovered once from the nasopharynx and (b) another case of a similar type of illness in which the virus was repeatedly recovered from the stools.⁶ We believe that the significance of the latter finding lies not so much in the confirmation of the now established fact that poliomyelitis may escape from the human body by the intestinal route as in the type of case which yielded the virus from this site.

Aided by grants from the President's Birthday Ball Commission for Infantile Paralysis Research.

CLINICAL MATERIAL AND METHODS

During the fall of 1937 a small outbreak of poliomyelitis occurred in and about the cities of New Haven and Meriden, Conn. Cases from this outbreak furnished our clinical material, and the results of twenty-two tests on fourteen patients appear in table 1. The results of nine tests on material from the nasopharynx and of thirteen on the stools are shown.

The Virus from the Nasopharynx.—Washings from the nasopharynx were obtained and tested during this epidemic from ten children (one of them was a contact

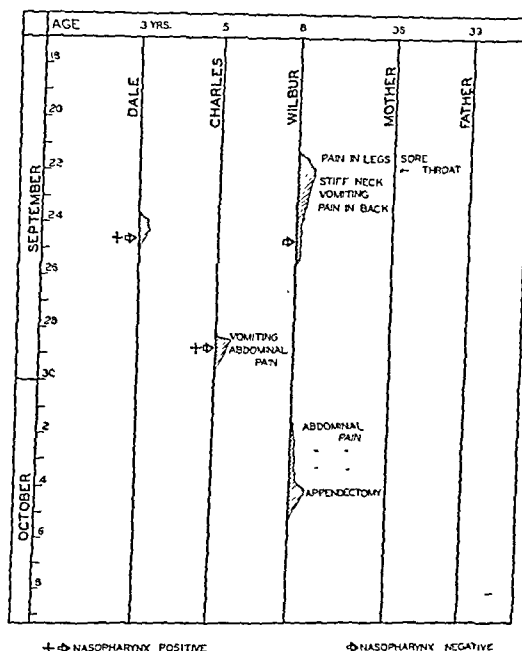

Chart 1.—Schematic diagram of Ch. family, which is composed of the parents and three children. Each individual in the family is portrayed by a vertical line; their ages appear at the top. Shaded areas on the vertical lines roughly show the amount of fever present during their illnesses. Dates along the left margin indicate the period with which we are concerned. Members of this family had been well during August and early September, although several cases of poliomyelitis had occurred in the neighborhood within this period. September 21, Wilbur, the oldest child, had fever, pain in the legs and stiffness of the neck. A diagnosis of nonparalytic poliomyelitis was made. Nasopharyngeal washings were obtained from this child on September 25, and also from the youngest child Dale (see arrows) who had acute fever for two days without other symptoms at this time. Four days later the third child, Charles, had fever, vomiting and abdominal pain, which subsided rapidly. Washings were obtained from him September 29, on which day his spine was somewhat stiff. One week after Wilbur's first symptoms had subsided he began to have abdominal pain and slight fever. October 5 an acutely inflamed appendix was removed. What relationship his appendicitis bore to the preceding illness is not clear. Unfortunately the pathologic specimen was placed in solution of formaldehyde; otherwise an attempt to isolate poliomyelitis virus from it would have been made.

and so does not appear in table 1). From these ten nasopharyngeal tests three positive results are recorded.

The first positive result in which the virus was recovered from the nasopharynx in this series was obtained from a boy of 7 years (John Wn.). He was the younger of two children in the same family (John and Robert), both of whom sustained fairly typical attacks of abortive poliomyelitis in mid-September 1937. The child John became ill September 15 with fever, drowsiness and a stiff neck. September 17 his brother Robert developed similar symptoms; namely, chills, fever, sore throat, with exudate on the tonsils, and a stiff back and neck. Neither illness lasted more than two days and in neither did paralysis develop. The nasopharyngeal washings that yielded the virus were obtained from John within twenty-four hours of the onset of his illness. Robert was not tested.

The other two patients in this series whose nasopharyngeal washings yielded the virus were members of the same family.⁷ As the clinical circumstances are more complicated than those just described in the Wn. family, they will be presented in the form of a diagram (chart 1).

Details of the technical procedures used for the determinations in this series of nasopharyngeal washings will appear in another publication. It may suffice to say that the nose and throat of the children were irrigated with sterile distilled water; the return fluid was collected, and to it 10 per cent ether was added as a bactericidal agent, prior to its inoculation into the monkey. Some of the washings were also concentrated by evaporation at low temperatures, according to a method first used by Kramer and his associates⁸ and recently modified by one of us.⁹ Only fresh animals were used for these inoculation tests. Daily temperature and exercise records were kept on all inoculated monkeys for a period of four weeks, unless it was found necessary to kill them earlier. If an animal showed any sign of experimental poliomyelitis or signs remotely suggesting experimental poliomyelitis, it was

of the virus in the throat has also served as a diagnostic test for detecting this mild form of the disease. This clinical picture is still inexact, and it is possible that in the absence of special laboratory tests, such as the demonstration of the virus, mild abortive poliomyelitis can be diagnosed only during an epidemic of poliomyelitis; that is, in close association with more definite cases. On the basis of our own experiences with this mild form of poliomyelitis, however, it can be described as an acute illness generally lasting from two to five days and characterized by fever, often by headache and vomiting and occasionally by abdominal pain and sore throat or by a stiff neck but often by a stiff back, which is detected only if one systematically attempts to elicit the "spine sign" by flexion of the vertebral column. Examinations of the spinal fluid have failed to show a pleocytosis in many of those tested.¹¹ We believe that these ill defined and brief types of illness are by far the commonest form of poliomyelitis. Indeed, they may outnumber the paralytic cases six or eight times,¹² and, as such, they are perhaps of more significance from an epidemiologic standpoint than are the paralytic cases.

TABLE 1.—Results of Nine Tests for Poliomyelitis Virus in the Nasopharynx and Thirteen in the Stools

Type of Case	Nasopharynx						Stool									Total
	Day of Disease					Total	Day of Disease								Total	
	1	2	3	4-6	7-10		1	2	3	4-6	7-14	15-25	26-75	76-100		
Abortive.....	2/2*	1/1	0/1	0/1	0/1	3/6	...	1/1	1/1	1/1	0/1	0/4	3/ 8	
Paralytic.....	0/1	0/2	0/3	0/1	0/2	0/2	0/ 5	
Total.....	2/2	1/1	0/1	0/2	0/3	3/9	...	1/1	...	0/1	1/3	1/3	0/1	0/4	3/13	

* 2/2 indicates that, from two out of two satisfactory tests, poliomyelitis virus was recovered.

killed at what seemed to be an appropriate time; histologic sections were examined from the medulla, cervical, thoracic and lumbar regions of the spinal cord, and an attempt was immediately made to pass the virus to another monkey. If any animal died during the four week period of observation from some cause other than poliomyelitis, the test was considered unsatisfactory. This occurred once with nasopharyngeal washings and five times with stools.

ABORTIVE POLIOMYELITIS

Apart from the general interest of finding the virus in the nasopharynx in these three cases is the fact that its presence there may be regarded as a diagnostic test for abortive poliomyelitis. In other words, in the absence of this finding at least two of these cases (exemplified by Dale and Charles Ch. in chart 1) might have been disregarded as unimportant or at least of uncertain type. For this reason we have examined with care the symptoms manifested in their illnesses and of other similar illnesses which occurred in this epidemic. The clinical picture which they presented has been found to be about the same as that which we have noted in previous epidemics¹⁰ and in which the presence

It is of particular interest, therefore, that the same type of case (the mild, abortive type) is also capable of yielding the virus from the stools.

THE VIRUS IN THE STOOLS

Thirteen stool specimens from eight patients were satisfactorily tested and three of these (all from the same child) yielded the virus. Again, the child in question was a member of a family¹³ in which another case of poliomyelitis had occurred. The clinical circumstances which transpired in this family group are presented in chart 2. Here is shown a family with three children, in which the oldest child (Teddy) had contracted severe, paralytic poliomyelitis early in October, and the youngest child (Daniel) contracted what appeared to be abortive poliomyelitis (onset October 18). Nasopharyngeal washings and stool specimens were obtained from all three children October 18 and 19. Some of the tests on this material were unsatisfactory, but from the diagram in chart 2 it will be seen that Daniel's first stool specimen, obtained on the second day of his disease, yielded the virus of poliomyelitis, and that this finding was repeated on two subsequent stools obtained on the eleventh and twenty-fourth days of his disease respectively. The positive stools from this child have been designated as 1, 2 and 3, the negative ones as 4 and 5. The virus was not recovered from

any of the nasopharyngeal or stool specimens from other members of the family. Unfortunately, the monkey receiving the nasal washings from Daniel died of streptococcal meningitis.

Samples of the three positive and two negative stools (or extracts from them) which had been obtained from Daniel Sk. were subsequently kept in the refrig-

19) 13.5 cc. of anesthetic ether was added as a bactericidal agent to make an approximate 15 per cent suspension. This was allowed to stand in a tightly stoppered flask overnight in the refrigerator. (Aerobic cultures on blood agar plates taken from the specimen at this time showed no growth.) A portion of this extract was then concentrated to about one fifth of its original volume by evaporation at low temperatures in the Flösdorf-Mudd apparatus.¹⁵ The concentrate represented 12 cc. One half of it was then inoculated into monkey 8-33, the doses being 1 cc. intracerebrally and 5 cc. intraperitoneally.

In later experiments (and also in a few experiments made at an earlier date¹⁶) we have found that material prepared essentially in the manner just described is often lethal for the monkey. Even though the inoculum may appear to be bacteria free, the animal often dies from necrosis of the brain, meningitis or bacteremia. In fact, of eight monkeys injected intracerebrally in this series of tests, five died prematurely. This fact led us to substitute intraperitoneal inoculations for intracerebral, because the peritoneal cavity will readily allow the injection of larger amounts of stool extracts than can be introduced into the brain, and because the peritoneum seems better able to withstand the immediate effects of this procedure than does the brain. By the intraperitoneal route, doses as large as 30 cc. of

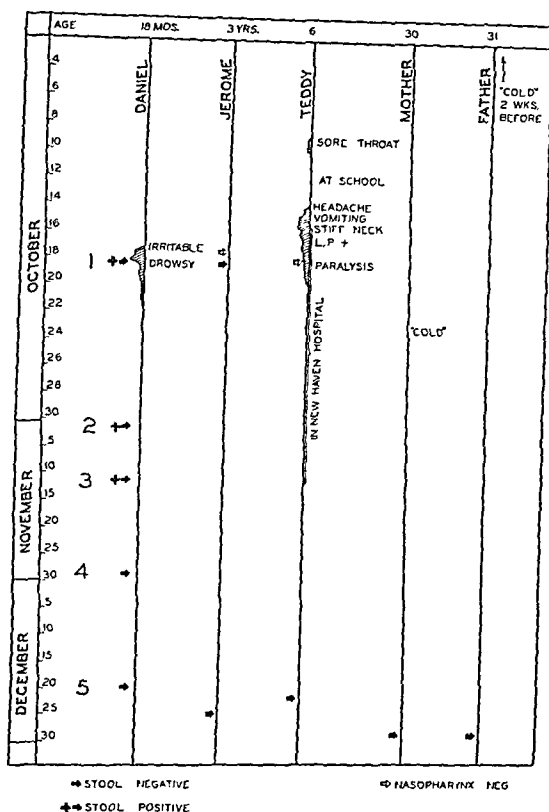

Chart 2.—Schematic diagram of Sk. family. The method of portraying events is the same as in chart 1. All members of the family had been well just before the onset of Teddy's illness, except that on September 24 or 25 the father "had a cold." October 8, Teddy, the oldest child, had a sore throat, and a week later he was hospitalized for severe paralytic poliomyelitis. Some of the details of this illness appear on the chart. L. P. + indicates that a lumbar puncture (performed October 17) revealed a pleocytosis of 160 cells. The youngest child, Daniel, aged 18 months, became ill October 18 with fever and listlessness. The fever continued for about four days. No evidence of muscular weakness was detected; his spine was slightly stiff October 20 and 21. Jerome, the middle child, remained well. The time at which stool specimens and nasopharyngeal washings were obtained appear in the form of arrows.

erator for some days or weeks, and the results of thirteen tests on material preserved from these five specimens appear in table 2. The fact that some of the tests on this preserved material were positive weeks after the collection of the specimens testifies to an extraordinary stability of poliomyelitis virus in the medium of human fecal material. This is another point of epidemiologic significance.

Methods of Preparing Stools for Inoculation.—Our first few attempts were exploratory,¹⁴ involving the trial of various procedures for preparing extracts of fecal material prior to its inoculation into monkeys. Brief details of these various procedures appear in table 2. Some of the technical details, which are omitted here, have been mentioned in the preliminary report of this work already referred to.⁵

In the first experiment (table 2, stool specimen 1 a) the following procedure was used: To 90 cc. of a dilute aqueous extract of Daniel's first stool (October

Chart 3.—Schematic diagram to indicate the period during which Daniel Sk.'s stools remained infectious. The clinical course of the mild illness is shown at the top. Not only did stools passed on the twenty-fourth day of illness contain poliomyelitis virus but the virus remained viable in this medium over a period of seventy-two days. Seventeen tests on this medium over a period of seventy-two days. Nine (previously unreported) tests were also made with nasopharyngeal washings at this time. They were collected from patients with abortive attacks within the first ten days of their illness. All of these tests were negative.

aqueous stool extract (originally containing 15 per cent ether) have been injected into one animal (table 2, stool specimen 3, tests b, c and f). Of twenty-seven

15. Flösdorf and Mudd.¹⁴ Paul.⁹
 16. Our only previous attempts to inoculate stool extracts intracerebrally were made in 1932. Seven monkeys were inoculated at this time with stool specimens from abortive cases of poliomyelitis. Six of these tests proved unsatisfactory because the monkeys died within eleven days of the inoculation. The seventh stool test was negative. Nine (previously unreported) tests were also made with nasopharyngeal washings at this time. They were collected from patients with abortive attacks within the first ten days of their illness. All of these tests were negative.

monkeys thus inoculated intraperitoneally only three have died prematurely. By this means (intraperitoneal inoculation of human stool extract) experimental poliomyelitis was produced in the monkey three times. This infectivity of human poliomyelitis virus for the monkey by way of an extraneural route (i. e., without intracerebral or intraneural inoculation) supplements our recent experiences with the intravenous¹⁷ and intradermal¹⁸ infectivity possessed by some strains of poliomyelitis virus.

A third modification of the technical procedures for preparing the inoculum was also used in some of the preserved extracts from stool specimen 3 (tests *d*, *e*, *j*, *k*). Here the material to be inoculated was precipitated with acetone, following a method used by Howitt,¹⁹ and the resuspended precipitate was inoculated intraperitoneally. This was done with the hope

point out that the diagram of the infectious aspect of this mild illness suggests a picture of an iceberg, seven eighths of the ominous structure of which is submerged below the surface of "clinical perception."

IDENTIFICATION OF THE VIRUS

Ever since the discovery of the poliomyelitis virus in 1909 there has been some confusion as to how frequently this virus has actually been isolated from a human source other than the spinal cord. Such confusion has been the natural result of changing criteria for the identification of poliomyelitis virus as a result of which some of the past claims for its isolation have now long been discarded. But it is still difficult to say which results should be accepted and which discarded, for there are no set diagnostic rules unless one makes them oneself. This we shall attempt in this report, not

that a concentration of virus might be thus effected. Material treated in this manner proved infectious in one instance (test 3 *d*, monkey 9-06).

Regardless of the methods employed, however, the virus was repeatedly found to be viable in the aqueous stool extracts from Daniel Sk. It was actually isolated six times. In one instance it was found to be viable in the stool seventy-four days after the collection of the stool specimen! The persistence of the virus in the stools not only in the patient during convalescence but its persistence *in vitro* appears in chart 3. The purpose of this chart is to illustrate the epidemiologic implications of this case. In it one sees the prolonged infectiousness of the child's stools, which existed *in vivo* and *in vitro*. This has been such an impressive feature to us, in view of the mildness of the clinical case involved, that we feel that its significance cannot be overemphasized at this time. It may even not be amiss to

because we believe ourselves to be arbiters in the matter but because some sort of criteria are necessary for any critical discussion of the subject.

In our own previous work on the nasopharynx in poliomyelitis²⁰ and in the present report, criteria for the recovery of the poliomyelitis virus from this site have rested on the following features: (*a*) on the production of a "clinical picture" in the inoculated monkey which is compatible with that of the experimental disease: i. e., after an appropriate incubation period there is the development of a train of characteristic symptoms usually exemplified by fever, excitement, tremor, ataxia, weakness and paralysis, the latter being generally associated with a fall in temperature; (*b*) when the animal is killed, lesions typical of experimental poliomyelitis must be found in the region of the anterior horn of the spinal cord, in lumbar as well as in cervical levels; i. e., lesions confined to the medulla are insufficient. Furthermore these lesions should be unequivocal and, besides presenting evidence of cell damage in the anterior horn, there must be perivascular infiltrations with mononu-

clear cells; (c) passage of the strain to a second monkey must be successfully accomplished.

None of the positive tests on human material described in this report or in any of our previous reports have been designated as yielding poliomyelitis virus without fulfilling these three criteria.²¹ A fourth criterion (d) which has been met in some of the tests in these experiments is that the suspected strain should not produce encephalitis or myelitis in laboratory animals other than the monkey; i.e., on intracerebral inoculation of rabbits, guinea pigs and mice (table 2). Such tests may be helpful in avoiding the possibility of confusing the virus of poliomyelitis with that of lymphocytic choriomeningitis, or perhaps with other viruses which are capable of producing an encephalitis in these animals.

For the further identification of this Sk. strain from the stools we have not yet^{21a} resorted to the use of neutralization (and reinoculation) experiments with other strains of poliomyelitis virus because of the questionable diagnostic value of this procedure. This questionability is due to the fact that well marked immunologic differences between some of the better known strains of poliomyelitis virus have been described.²²

Reference has already been made to the fact that there has been some confusion as to how frequently the virus of poliomyelitis has actually been isolated from the human nasopharynx or the intestinal tract. This confusion is justified and difficult to dispel. If the somewhat rigid criteria for the identification of poliomyelitis virus, which we have outlined in this paper, are applied to most of the data existent in the literature, very few of the previous reports of its recovery from extraneural human sources would be found to be acceptable. Nevertheless, all the tests, whether positive in their outcome or questionable or negative seem to be worthy of reanalysis at this time because it is important to determine whether the literature reveals information as to whether it has been easier in the past to isolate the virus from the nasopharynx than from the intestinal tract.²³

21. In one "negative" test in this series on stool extracts (3 f) two of our criteria were partially fulfilled. In the test animal (monkey 9-09) fever developed but paralysis was not detected. Extensive lesions were subsequently found in the spinal cord, but unfortunately material from this animal was not saved in glycerin and so a passage could not be tried.

21a. Since this paper was submitted for publication these tests have been partially completed and will be reported on subsequently.

This is difficult, for it is not known with any degree of accuracy what the ratio of positive to negative results has been in tests of this kind, because failure to find the virus in a given site may be due more often to an inadequate method of demonstrating it than to its absence. Furthermore, many negative attempts have been casually described and many have probably not been published at all. From the nasopharynx, however, one finds that some 241 tests are recorded in the literature which can be used in estimates on active cases or convalescents. (This includes a few tests done on tonsillar emulsions from fatal cases. It does not include tests in which the approximate day of the disease is not specified, or the many tests that have been done on healthy contacts.) To these 241 tests are added those reported in this article, which appear in table 1, and also a small series of previously unpublished tests which were made by two of us in 1932.¹⁶ Using a good deal of liberality in the interpretation of some of the results of this whole series of 260 nasopharyngeal tests, one finds that thirty of them offer acceptable evidence of the isolation of poliomyelitis virus from the nasopharynx. On this basis we also find that roughly about 15 per cent of these tests on the nasopharynx have been positive if made during the first ten days of the disease, and 5 per cent have been positive if made in the subsequent six weeks.

With stools or colonic washings a smaller number of experiments are recorded. About eighty-six tests are described (including our own) and from a similar rough estimate we find that about 27 per cent have yielded the virus in the first ten days of the disease and about 12 per cent during the first few weeks of convalescence. In other words, this series reveals the surprising fact that it seems to have been almost twice as easy to find the virus in the stools during early stages of the disease as it has been to find it in the nasopharynx, and more than twice as easy during late stages.

These facts force us to reconsider whether poliomyelitis may not be, to some extent at least, an "intestinal" disease. By this term we do not imply that the virus necessarily enters the body by way of the gastrointestinal tract, for the data at hand do not give any information on this point; they merely emphasize the importance of the feces as a medium of exit. There are a number of supplementary epidemiologic features which this reconsideration of poliomyelitis as an intestinal disease brings up. Foremost among them is the seasonal prevalence of poliomyelitis in temperate climates. Like typhoid and dysentery, it is essentially a summer disease. Another feature, perhaps not so well known, is the presence of lesions in association with the intestinal tract, such as mesenteric lymphadenitis or lesions in the lymphoid tissues of the lower part of the ileum and the cecum. Some of these seem to have been noted more than fifty years ago.²⁴ Recently they have received renewed attention from Landon and Smith,²⁵ who have described them in their large series of human autopsies. It is unknown, of course, what the pathogenesis of such lesions is or what their actual relationship to poliomyelitis virus may be, but at least there seems to be enough evidence here to attract attention to this part of the body in an effort to unravel some of the obscurities which exist with regard to the

25. Landon, J. F., and Smith, L. W.: Poliomyelitis, New York, Macmillan Company, 1934, p. 25.

pathogenesis of human poliomyelitis. It also may not be amiss to say that many of the implications here set forth go to support the contentions of Toomey,²⁶ who from a different type of evidence has long supported the idea that poliomyelitis is an intestinal disease.

But whether poliomyelitis is an intestinal disease or whether it has a "gastrointestinal phase" is not our main thesis. One of the main points is that all four cases described in this report which yielded the virus either from the nasopharynx or from the stools were abortive cases. This fact continues to emphasize, to us at least, that the crux of many problems of the epidemiology of poliomyelitis may well rest on the much neglected abortive case, not only during its acute but also during its convalescent stage. That the stools in these mild and generally unrecognized cases (which may outnumber the paralytic cases eight times) may be infectious over a period of three weeks places these patients almost in the status of "healthy carriers." Furthermore, that the virus may survive in vitro in the stools for ten weeks suggests that during an epidemic a high degree of pollution of sewage with poliomyelitis virus could readily occur. In fact, one could almost term this hypothetical degree of sewage pollution as "massive."

SUMMARY

1. Poliomyelitis virus was found in four clinical cases of poliomyelitis: three from the nasopharynx in three cases and three times from the stools in one case.

2. Human stool extract for inoculation into monkeys does not have to be injected intracerebrally in order to produce the experimental disease.

3. The attacks in all cases which yielded the virus were mild and nonparalytic. It is probable that some of the attacks might not have been regarded as examples of poliomyelitis without this finding.

4. The child who showed virus in the stools was ill for only three or four days, and yet the virus persisted in the feces for at least twenty-four days from the onset of his mild illness. It also remained viable for ten weeks in one of his stools which was kept in the refrigerator. Such facts suggest that during an epidemic of poliomyelitis these common, mild and often unrecognized forms of the disease may be responsible for a high degree of pollution of sewage with poliomyelitis virus.

Time and Ethical Standards.—The medical profession has never allied itself as a profession with any political group. It has and still does recognize the fact that political entanglements mean restrictive hobbles on the legs of medical progress. It asks only to be left free to ply its craft, unhampered by forces unqualified either by training or ethical standards to say what is best for the patient. These ethical standards have stood the test of time and must be maintained. It is a fact that political domination of medical practice is having tremendously devastating influence on the type and quality of medical service wherever such conditions apply. Political expediency and bureaucratic control do not tend toward elevation of professional standards. America was not purged of low-grade medical schools and diploma mills until the medical profession took a firm stand and established certain requirements for medical schools. It was a long, slow fight against political forces to rid the country of the menace of inadequately trained physicians. This was primarily in the interest of the public.—Borzell, Francis F.: *The Medical Profession and the Social Worker, Pennsylvania M. J.* **41**:683 (May) 1938.

CUTANEOUS ABSORPTION OF SEX HORMONES

CARL R. MOORE, PH.D.

JULE K. LAMAR, PH.D.

AND

NAOMI BECK, A.B.

CHICAGO

Despite some previous reports on the effects of hormones when applied to external surfaces,¹ there is yet a lack of appreciation of the readiness with which such substances are taken up by the skin and become effective in the body. This is of importance because hormones are at present available in ordinary commercial items such as face creams. A realization of their ready entrance into the body and some measure of their effects after entering the body should therefore be understood. The following brief account is devoted to presenting some of our experiences in applying both androgens and estrogens in a lanolin-like menstruum or cream to the skin of experimental animals.

APPLICATION OF ANDROGENS

We have employed testosterone and testosterone propionate in a concentration of 50 mg. per ounce of cream.² Treatment has usually been limited to one daily application on areas of shaved skin of from 2 to 6 square inches on the back of the neck and shoulders or on the belly. Shaving is not essential, since rubbing the substance into the hair over the same area each day is almost equally effective. Weighed or measured amounts of cream have been such that on the average 0.6 mg. of the pure chemical androgen is contained in each application.

1. Normal male guinea pigs when properly stimulated on the head by an alternating electric current invariably void a seminal discharge containing spermatozoa and the mixed secretions of the accessory reproductive glands. The ejaculate becomes a coagulated, rubber-like mass within five minutes after its discharge. Castrated males are incapable of ejaculation, since the function of the accessory reproductive glands is under male hormone control.³

Guinea pigs castrated before sexual maturity and treated one year later received daily applications of ointment on a small area of skin on the back of the neck. Coagulable ejaculates were obtained on electrical stimulation by the seventh day of treatment. Stimulations each successive week resulted in increased amounts of ejaculate up to the fifth stimulation, when ointments were discontinued. Subsequent weekly discharges were progressively smaller and disappeared on the fourth week after cessation of treatment.

2. Daily applications of ointment on the neck of castrated male rats, on bare skin or in the hair, offered a complete substitution for the internal secretion of the testes, as judged by the fresh weights of seminal vesicles and prostate gland.

Ten male rats, 4 months of age, were grouped so that eight animals were castrated. Five of these were

From the Hull Zoological Laboratory, the University of Chicago. This investigation has been aided by a grant from the Rockefeller Foundation to the University of Chicago.

1. Burrows, Harold, and Kennaway, N. M.: *Am. J. Cancer* **20**:48 (Jan.) 1934. Fussänger, R.: *Med. chem. Ztschr.* **2**:194, 1934. Burrows, Harold: *Am. J. Cancer* **23**:490 (March) 1935. Deanesly, R., and Parkes, A. S.: *Proc. Roy. Soc. London, s. B.* **124**:279 (Dec. 7) 1937. 2. Drs. Gregory Stragnell, E. Schwenk and Max Gilbert of Schering Corporation provided ointments containing these androgenic substances. 3. Moore, C. R., and Gallagher, T. F.: *Am. J. Anat.* **45**:39 (Jan.) 1930.

treated directly, two were treated indirectly and one remained an untreated castrate control. These ten animals, cited in table 1, illustrate several points. The animals were confined in three cages: one cage contained two normal and one castrate control; the second cage contained five castrates, four of which were anointed daily, while the fifth received treatment only from contact with treated cage mates; the third cage contained two unshaven castrates, only one being treated with ointment. Castrates were treated on the day of orchidectomy and for nineteen consecutive days. All animals were killed on the twentieth day of the experiment.

Attention to table 1 reveals that castrated animal 3, compared with normal controls 1 and 2, had experienced marked regression in the fresh weight of accessory reproductive glands within the twenty days of castration. Castrate 8, though receiving no direct application of the hormone, was caged with four castrates subjected to daily treatment with the ointment containing testosterone. The tendency for rats to sleep in compact groups provides contact with treated cage mates and

hence an indirect exposure to the hormone. Castrated animals 9 and 10 were not shaved and only the former one was treated; animal 10, therefore, was exposed to the hormone only through contact with its single cage mate, which received daily treatments always on the same area of hair.

Examination of the data in table 1 demonstrates clearly the following facts: 1. Single daily application of the hormone-containing cream carrying 0.6 mg. of testosterone maintains weights of accessory reproductive organs equivalent to those of untreated normal controls. Cutaneous absorption appears about equally good on the neck or belly. 2. Two daily applications (total 1.2 mg.) causes the seminal vesicles to be of the order of 50 per cent greater than those of the normal controls. 3. Bare skin is not essential for absorption of hormone, since daily application to the same area of hair is only slightly less effective than on bare skin (compare animal 9 with animal 5 or 7). 4. Each untreated castrated male associated with treated cage mates possessed seminal vesicles 100 per cent greater than castrates associated with untreated males only. Absorption from contact has occurred in five repetitions of these experimental conditions and, in some cases not cited, seminal vesicles were only slightly less developed than in cage mates treated directly.

3. Treatment of castrated male rats during the most rapid period of growth of the accessory reproductive organs readily maintains a normal rate of growth of

these structures in castrate males with either the free hormone or the propionate, or it causes a much greater growth than in control litter mates. Thus, castrated males treated once a day from day 30 to day 50 with 0.6 mg. of free hormone possessed seminal vesicles weighing more than five times those of normal litter-mate controls. Castrates treated twice a day with testosterone propionate (total daily 1.2 mg.) from day 50 to day 70 possessed seminal vesicles considerably heavier than those of normal control litter mates.

4. Inquiry has been made with regard to the relative effectiveness of the free hormone and the propionate when applied as a cutaneous ointment in two groups of males: In group A, consisting of eight males 5 months of age, comparison was made of the accessory reproductive organs of two normal controls, two untreated castrates, two castrates receiving ointment containing free hormone twice a day (daily total 1.2 mg.) and two castrates receiving a like amount of propionate-containing ointment. The experiment was terminated on the twentieth day. Seminal vesicles of each hormone-treated male were slightly larger than those from normal controls and ten times the weight of those from untreated castrates; those from animals treated with the free hormone averaged 50 per cent greater than those from castrates treated with the propionate.

Group B, consisting of ten young males from 3½ to 4 months of age, were all castrated. Five were given eighteen single daily treatments on the neck with ointment carrying 0.6 mg. of free testosterone, beginning the day following castration. The second five were similarly treated with ointment carrying 0.6 mg. (daily) of testosterone propionate. All were killed on the day following the last treatment and the fresh weights of accessory reproductive organs were determined by means of a torsion balance after dissection under a binocular microscope. The average weight of the seminal vesicles of the five testosterone-treated males was 584 mg., while the average of four treated with propionate was 220 mg. Owing to slight loss of seminal vesicle secretion during dissection from one male treated with propionate, this animal was excluded from the average weights. This average figure expresses a real difference in effectiveness, since all males on free hormone possessed seminal vesicles that were heavier by 100 mg. than any male receiving the propionate treatments.

It is evident that when applied as an ointment the free hormone is more effective than the combined form.

5. The relative effectiveness of free testosterone, when given by subcutaneous injection in oil and when applied as an ointment on the skin, was investigated on but a single litter of animals; nevertheless the results were convincing. In a six male litter four animals were castrated on day 30; two castrates received daily subcutaneous injections of 0.6 mg. of testosterone in 0.2 cc. of sesame oil while the other two castrates received one daily application of ointment carrying 0.6 mg. of testosterone. The animals were killed on day 50. Seminal vesicles of normal litter mate controls weighed 67 mg., those receiving daily injections weighed 158 mg., while those receiving the same amount of free hormone by ointment weighed 398 mg. Thus cutaneous application of testosterone produced seminal vesicles weighing more than double those from treatment by injection and almost six times more than those from untreated normal litter mates.

6. Since testosterone or the propionate has been found highly injurious to the testes of young growing male rats when given by subcutaneous injections,⁴ it became of interest to investigate their possible effects when applied in an ointment.

A litter containing seven males was selected for treatment from day 22 to day 37 and killed on day 38. Three untreated controls occupied one cage while four others were caged together, three of which received treatment and the fourth only indirect treatment through contact with treated cage mates. Each treated male received two daily applications of testosterone propionate on the neck (total daily dose 1.2 mg.). On day 38 the average fresh weight of testes of the three ointment-treated males was 45 per cent below the weight of the untreated controls; the weight of testes of the untreated male associated with treated cage mates was 73 per cent below that of the normal control.

Thus, as with injected hormones, testes of young growing males are gravely injured when testosterone propionate is applied as a cutaneous ointment. The greater injury appearing in the indirectly treated male receives its explanation in the observations of Moore and Price⁴ that injury to the testis from injected testosterone propionate is inversely proportional and not parallel with dosage. That this animal actually received smaller amounts of hormone than the three cage mates treated directly is shown by the fact that its seminal vesicles were approximately one half the weight of those from males treated directly. Here also the smaller dosage produced the more severe testicular injury. Though these animals were at an age when sperm heads should have been present,⁵ and they were present in the testes of all untreated controls, the testes of the more severely affected male were entirely devoid of sperm heads and those least affected had materially fewer sperm heads than normal.

APPLICATION OF AN ESTROGEN

The effects of chronic cutaneous application of estrogen have already been noted by Burrows and Kennaway,¹ who employed a solution of estrone in benzene for periods up to several months. They determined that estrone was absorbed sufficiently to produce great enlargement and metaplasia of the prostate gland in mice.

Our experiences with application of estrogens as an ointment have been limited to observations made on the effects of a commercial face cream recommended for use by normal women to prevent or eradicate facial wrinkles. It is claimed that the preparation contains estradiol in a concentration of 0.625 mg. per ounce, that its effects are limited to the skin and that it produces no effect on internal structures of the body. It is recommended that one-half spoonful a day should be utilized for rubbing on the face, neck, hands and arms. This amount would carry approximately 40 micrograms for each daily application. Proper results are said to be obtained only by rigorous adherence to daily application and that results should be noticeable within about thirty days.

Since penetration through the skin occurs so readily in the case of testosterone and testosterone propionate, being even more effective for the uncombined hormone than similar amounts introduced in subcutaneous injection, it is of interest to inquire whether estradiol has an effect on the skin and yet exerts no effect on internal organs.

The face cream was purchased in the open market. It was applied in doses (weighed amounts of cream) such that if the labels are correct we used in our experiments one-fifth the recommended daily dose for women, which carried approximately 8.2 micrograms of estradiol.

1. A single daily application for two days to a 3 square inch area of shaved skin on the neck of spayed female rats induced cornified estrous smears within forty-eight hours. Two or three applications failed to hasten the reaction.

2. Normal male guinea pigs from 3 to 4 months old received respectively one, two and three daily applications of the cream on the neck during a period of three weeks. Measurements of the nipple of the mammary gland during the course of the experiment revealed that the nipples of animals receiving treatment once a day doubled their height by the second week; two or three daily treatments caused an increase in the height of mammary nipples of from three to five times in the course of three weeks of treatment. The nipples became

TABLE 2.—Effect of One Daily Application of Face Cream Containing Estradiol on Uterine Weight in Spayed Rats

turgid and the areolas prominent, and the external portion of the apparatus exceeded that of normal females of similar age.

3. Female rats were subjected to ovariectomy on day 39 and face cream was applied once a day on the neck until day 59, when the animals were killed and their uterine weights compared with normal litter mate controls and with untreated spayed females. In table 2 A the average uterine weight from two litter mate controls was approximately 200 mg. (the heavier fluid-filled proestrus uterus is naturally temporarily heavier because of fluid), that from spayed treated animals 225 mg. and the spayed untreated uterus 19 mg. The vaginal smear of each spayed treated female was heavily cornified.

Uterine response for older females following ovarian removal and treatment with face cream is illustrated in table 2 B; single daily applications on the neck were given for nineteen days with death on the day following the last application. One sees that the weight of the uterus of each of five spayed treated females is greater than the heaviest uterus among the five control females; average uterine weight for the five spayed treated females is 48 per cent greater than the average of five normal control uteri.

Such treatment of spayed females, therefore, more than substitutes for the loss of the ovaries.

4. Moore, C. R., and Price, Dorothy: *Anat. Rec.* **71**: 59 (May) 1938.
5. Moore, C. R.: *Am. J. Anat.* **59**: 63 (May) 1936.

4. It was of interest to examine the effect of the face cream on normal male rats. The estrogenic substance from extracts of human placentas and human pregnancy urine has been found to be highly injurious to the testes when administered by subcutaneous injection.⁶

In a litter containing five males, three were treated once a day with one-fifth the recommended daily dose from day 37 to day 56 and killed on day 57. The average weight of the testes of two untreated controls was 2.179 Gm., that of three males treated with face cream 0.4127 Gm., or a reduction in the weight of the testes in treated males of 81 per cent as compared with normal litter mate controls. The weight of seminal vesicles in normal controls was 179 mg. as against 16 mg. for treated males, or a reduction of 90 per cent.

COMMENT

The results of experiments here cited are important for the demonstration of the ease with which sex hormones are absorbed through the skin rather than for presenting hitherto unknown effects of the hormones themselves. Many methods of administration of hormones have been studied in an attempt to reduplicate the activity of the intact sex glands as regards both the proper substances to be employed and the proper release of the substances in the body. Subcutaneous injections in oil have served more frequently as methods of application, but oral administration, nasal sprays, vaginal suppositories, cutaneous application and subcutaneous implantation of crystalline pellets have been used by various workers.

Deanesly and Parkes¹ have investigated various methods of application and consider that the subcutaneous implantation of pellets of crystalline material is perhaps the most efficacious means. By such procedures it is believed that absorption in body fluids is both slow and continuous and that the high and low concentrations arising from daily subcutaneous injections are avoided. It is likewise recognized that the absorption rate of hormones varies with the rise of different concentrations and different oils.

The results presented here call especial attention to the ease with which hormones may be applied as ordinary ointments as well as the readiness with which the substances are passed into the body and produce such effects as are known to follow subcutaneous injections in oil. It is evident from the experiment that ordinary testosterone is more effective than the propionate when the substances are applied as ointments on the skin. Similarly there is good evidence of greater effectiveness of testosterone when applied to the skin as an ointment than when injected subcutaneously in small quantities of sesame oil. It is presumed that these phenomena reveal a more gradual and continuous absorption through the skin than occurs when administration is by subcutaneous injections, and it is also apparent that the recognized effective superiority of propionate over the free hormone, in evidence from subcutaneous administration, is reversed when application is by means of ointment.

The ease with which cutaneous ointments containing hormone are applied and the tremendous influence that these substances have when taken into the body more or less continuously present the possible menace that would apply to any powerful drug that is easily procured and administered. It raises decidedly the question of the

propriety of including such substances in face creams for use by normal women on the presumption that it is beneficial in removing or warding off wrinkles and that all effects are limited to the skin. When one-fifth the recommended daily dose applied on a relatively very small area of skin causes in normal male guinea pigs a doubling or tripling of the height of the mammary nipple within a period of from two to three weeks, when it maintains the functional state of the uterus in ovariectomized female rats, when it brings on vaginal coagulation or when it exerts profound injury on the testicles of normal male rats, it would certainly appear to be demonstrated that the effectiveness of the substance in question extends beyond the surface of the skin.

The fundamental question for consideration, and one that would appear to merit closest attention, is the influence that such administrations may have on the internal regulatory mechanism of the normal female reproductive functions. Much has already been written on ideas concerning the controlling mechanisms of reproductive cycles. Whereas the ovarian hormones play a fundamental characteristic role, this does not imply a more or less continuous liberation of hormone in the body but rather a series of periodic changes characterized by high and low concentrations. The sex glands are under an extraneous control believed to be largely centered in pituitary activity, and this in turn appears to be closely regulated by concentrations of gonad hormones. It is well known that administrations of estrogens to experimental animals disturb the normal controlling mechanisms, and in the animals here cited small amounts of the alleged wrinkle-removing face cream certainly maintain the animal in continuous vaginal estrus.

When hormone therapy is indicated, administration as skin ointments may prove to be the method of choice.

SUMMARY AND CONCLUSIONS

1. Testosterone or testosterone propionate applied on the skin as an ointment is readily absorbed and either maintains the accessory reproductive organs of castrate males in a normal reproductive state or stimulates their development precociously in the young or decidedly above the normal levels in adults.

2. These androgens, so administered, exert effects similar to those obtained following subcutaneous injections. They (a) maintain reproductive accessories in castrate males at all ages, (b) reconstitute castrated guinea pigs within seven days of treatment to a state of producing coagulable ejaculates on electrical stimulation of the head and (c) produce injuries to testes of normal growing young male rats.

3. Face cream (stated to contain estradiol) sold commercially and recommended for the removal of wrinkles from normal women has decided internal effects when applied daily on the skin of experimental animals. Such treatments (a) stimulate mammary development on normal male guinea pigs, (b) induce cornified vaginal estrous smears in spayed female rats, (c) maintain or increase normal growth of the uterus in young or mature spayed rats and (d) reduce the weight of testes by 80 per cent and the weight of seminal vesicles by 90 per cent in young male rats in comparison with normal litter mates.

4. These results both emphasize the efficiency of applying hormones in a skin ointment and at the same time suggest caution in the use by normal persons of articles containing these active principles.

as to whether the symptoms of the patient were really after-effects of the encephalitis or whether they had been present in the same degree before the illness; in some instances it was evident that symptoms during the acute stage of the disease were included in the report, and in other instances it was not entirely clear as to whether the symptoms noted were observed during the acute stage or at the time of the follow-up examination.

It was then decided by the committee of the Metropolitan Health Council to make a second follow-up study on all the surviving patients, city and county.

A questionnaire was prepared, simply worded to avoid misinterpretation of the questions, and sent to 874 supposedly surviving patients in the city and county.

The results of the second follow-up study, which was carried on during the fall of 1934 and the spring of 1935, are given in table 2.

After an analysis had been completed of the results of the second follow-up study, it became obvious to the committee that it would be necessary to undertake a third follow-up study primarily for the purpose of making a reexamination, at some future date, of those

reported their health improved. Therefore, a total of 66 per cent felt that they had experienced no impairment of health as a result of the disease. Only twenty-two patients, or 6⅔ per cent, felt that they were physically unable to resume their previous occupation. An analysis of these cases showed that six of these patients were above 60 years of age, and the infirmities of age of these patients may have been as important as the residuals of encephalitis in rendering them physically unable to work.

* Some of these complaints existed prior to attack of encephalitis.

† Eleven per cent of all patients had some type of muscular tremor. No advanced parkinsonism was seen.

patients who presented not only residual symptoms but also organic residues. There were thirty-one such patients.

The health commissioner, therefore, appointed a special committee for this purpose, consisting of an internist, a pediatrician, a neurologist and the assistant health commissioner, and plans were made for a third reexamination of these thirty-one patients. The results of the third follow-up study are shown in table 6.

The important facts to be noted in the figures given in the various tables are the following: The mortality, including deaths since the epidemic subsided, was 18.7 per cent. Of 331 patients reexamined, 141 felt as well as before the attack of encephalitis and seventy-nine

ism. The organic residuals found on physical examination were limited to eighteen patients, or only 5.7 per cent of all patients examined.

COMMENT

These observations may be contrasted with those previously reported for cases of the winter type of encephalitis. A brief summary of comparative figures from the reported studies of Parsons,¹ Main,² Reys,³ the Italian Public Health Reports,⁴ von Economo,⁵

1. Parsons, A. C.: *Proc. Roy. Soc. Med.* 21: 1307-1318 (June) 1928.
2. Main, Ashie: *J. Hyg.* 31: 162-189 (April) 1931.
3. Reys, L.: *L'encephalite epidemique*, Paris, 1922.
4. Italian Public Health Reports, quoted by Stern.⁴
5. von Economo, Constantin: *Die Encephalitis lethargica*, Berlin, Urban & Schwarzenberg, 1922.

Stern,⁶ Howe,⁷ Ziegler⁸ and Kaneko and Aoki⁹ are given in table 9. The statistics of Kaneko¹⁰ for the type B encephalitis are also included.

While the mortality varies widely in the series reported, it would appear that the mortality reported by the European observers for the winter type of the disease, with the exception of the reports of Reys and Stern, is higher than that of any of the American observers. The study reported by Howe concerned children living near Baltimore. The figures given by Ziegler relate to patients who came to the Mayo Clinic largely for the residuals of the chronic stage of the disease. Hence the mortality of the acute stage is largely eliminated. The mortality of the summer type of encephalitis in Japan is higher than that of the St. Louis summer epidemic.

The percentage of complete recovery of health is apparently much higher in the summer type of the disease than in the winter type. Two thirds of all patients studied in the St. Louis outbreak reported restoration of health. In Japan the percentage of residuals found was very low—much lower in fact than we have found in the present series. Of the figures on the winter type of the disease, the most favorable are those of Howe, who found that 51.8 per cent of the children surviving the disease recovered. The very low figure for recovery in the series of Ziegler is due to the fact already noted that he was dealing largely with patients in the chronic stage showing marked residuals and not a group of patients studied from the time of the acute attack. Forty-two per cent of our patients reported not only no complaints attributable to encephalitis but no complaints at all.

One of the most encouraging features of the present study is the very small percentage of total disability found; namely, 6⅓%. This is in striking contrast with all studies of the winter type of encephalitis, in which the total disability varies from 19.1 to 70 per cent. This difference is apparently due in a large part to the fact that so far severe parkinsonism has not been noted as a residual. It is true that 11 per cent of our patients complain of muscular tremors, but in most instances these are slight and not disabling. While it is still too early to say that parkinsonism will not develop, the situation at the present time is most encouraging in this respect. While no accurate figures are available, the winter type of encephalitis, when occurring in the vicinity of St. Louis, has a high percentage of residuals of parkinsonism. This would appear to be an important difference in the two types of encephalitis.

It is noteworthy that the organic residuals actually observed on physical examination were present in but 5.7 per cent of all cases and were often not of great severity.

On the other hand, subjective nervous complaints of slight or moderate severity are fairly frequent residuals. In the cases included in the present study, nervous excitability was reported in 42 per cent, irritability was a complaint in 45 per cent, loss of memory was also a common residual, being reported in 38 per cent of all cases, and drowsiness occurred in 27 per cent. Some of these complaints were present prior to the attack of

encephalitis. Subjective nervous complaints, nevertheless, would appear to be by far the most common residuals of the St. Louis type of encephalitis. They are of sufficient severity to cause complete or serious incapacity in but few instances.

The most important disturbance of the motor nervous mechanism noted was difficulty in walking. This was reported in about 25 per cent of all cases. It was described as an unsteadiness of gait or as difficulty in walking in a straight line. This complaint was seldom of sufficient severity to incapacitate the patient.

SUMMARY

A restudy of patients in St. Louis and St. Louis County who suffered an attack of encephalitis in the summer of 1933 shows complete recovery of 66 per cent of all the patients, but only 6.3 per cent are physically unable to resume their previous occupations. Severe parkinsonism so far is quite uncommon as a residual. Mild subjective nervous complaints are the most common residuals, particularly headaches, nervous irritability, loss of memory and drowsiness.

MENINGO-ENCEPHALITIS IN MUMPS

HERMAN FINKELSTEIN, M.D.

WEST ORANGE, N. J.

It is fairly well known that meningo-encephalitis may occur during the course of mumps, but its frequency has never been ascertained. It is my purpose in this paper to show that meningo-encephalitis occurs quite frequently in mumps, though usually with such mild symptoms that unless one resorts to spinal punctures at the slightest indication the diagnosis will not be made in many cases.

During the period of two and a half months in October, November and December 1937, routine spinal punctures were done on practically all patients with mumps admitted to the Willard Parker Hospital with the exception of adult patients and patients with mumps that occurred simultaneously with some other disease. About forty patients had spinal punctures done as soon after admission as was feasible. A complete physical and neurologic examination preceded the spinal puncture. All spinal fluids were examined in Dr. Josephine B. Neal's laboratory of the health department and in the laboratory of the Willard Parker Hospital. Sixteen of these cases in which abnormal spinal fluids were found are being reported. They were divided into three groups, depending on the severity of the symptoms: group A, severe; group B, mild; group C, symptom free.

GROUP A

The four patients in group A, at some time during the first week of their illness, had severe clinical signs and symptoms of involvement of the central nervous system. These patients presented extreme drowsiness, severe headache, malaise, fever and vomiting. They sometimes presented abnormal neurologic signs, such as a positive Kernig, a positive Brudzinski and nuchal rigidity. The symptoms persisted for several days, the lethargy lasting from three days to a week. Headache persisted for from four to five days in each of the four cases. Sedatives were resorted to, since spinal punctures did not relieve the patients of their headaches.

Patient 3, while convalescing, suddenly had a psychosis and was transferred to Bellevue Hospital for observation, where the diagnosis toxic psychosis was made because the patient was confused for a few days, but it cleared up rapidly. The psychosis was attributed to the mumps.

GROUP B

The six patients in group B had mild symptoms, including slight headache, listlessness, anorexia and slight fever. These symptoms were so mild and of such short duration that, under ordinary circumstances, one would not consider the diagnosis of meningo-

Physical Examination, Course and Spinal Fluid Changes in Three Groups.

Date of Onset of Case	Date of Mumps	Date of Spinal Tap	Physical Examination on Admission	Course	Spinal Fluid
GROUP A					
1	12/23	12/26	Boy, aged 9 years, temperature 103 with 3 day history of mumps, sore throat, fever; convulsions on admission; pupils widely dilated and did not react to light; abdominal reflexes absent	Semicomatose and disoriented; temperature normal after 5 days; mentally normal 1 week after admission; reflexes normal; could not take food or fluid by mouth for 4 days; vomited when forced	Cells 60, 98% monocytes; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
2	12/26	12/29	Boy, aged 6 years, temperature 104; 3 day history of mumps; very drowsy; chills; could not be aroused on admission; neurologic examination negative	Temperature normal after 3 days; mentally clear after 3 days	Cells 240, monocytes predominate; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
3	12/13	12/20	Youth, aged 17, with 7 day history of fever, mumps and orchitis, temperature 105.2 on admission; acutely ill, markedly drowsy, difficult to arouse, headache, moderate nuchal rigidity, Kernig and Brudzinski negative	Temperature dropped to normal in 24 hours; drowsiness and headache lasted about 72 hours after admission; during third week of convalescence a psychosis developed; transferred to Bellevue Hospital for observation	Cells 60, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus; fluid clear
4	12/15	12/17	Woman, aged 25; temperature 102 on admission with 2 day history of mumps; nausea, vomiting, abdominal pain; very drowsy; could not be aroused; neurologic examination negative	Temperature normal in 48 hours; headache severe and drowsiness lasted 4 to 5 days; showed psychic changes on fourth day after admission; lasted 2 to 3 hours	Fluid clear; cell count unsuccessful; monocytes increased in smear; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
GROUP B					
1	10/28	11/1	Boy, aged 3 years; temperature on admission 102; not ill; 1 day history of mumps; neurologic examination negative	Temperature normal 1 day after admission; 11/1 temperature rose to 101; became drowsy; neurologic examination negative; after 24 hours temperature normal, symptoms relieved	Fluid hazy (slight); cells 170, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
2	10/28	11/3	Boy, aged 9 years; temperature 101; not ill; 1 day history of mumps; neurologic examination negative	Temperature normal 11/2, then rose sharply to 104; had slight headache, slight drowsiness, vomited once; slight nuchal rigidity; slight Kernig and Brudzinski; temperature normal and signs and symptoms disappeared in 24 hours	Fluid clear; cells 140, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
3	11/21	11/23	Girl, aged 8 years; temperature 102; 3 day history of mumps; not ill on admission; neurologic examination negative	11/25, temperature normal in a. m., in p. m. temperature rose to 104; no complaints except slight drowsiness; neurologic examination negative; temperature normal 12/3	Fluid clear; cells 25; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
4	12/21	12/27	Boy, aged 4 years; temperature 99 on admission; 1 day history of mumps; not ill; neurologic examination negative	Temperature normal until 12/26 when it rose to 103; slight drowsiness, no other complaints; neurologic examination negative; temperature normal on 12/31	Fluid slightly hazy; cells 245, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
5	11/5 (a) 11/12 (b) 11/17		Boy, aged 7 years; temperature 99; 5 day history of mumps; not ill except for slight sore throat; neurologic examination negative	11/11, had slight headache and drowsiness, vomited twice; temperature normal 11/13, at which time patient was symptom free; neurologic examination negative	(a) Fluid hazy; 98% monocytes; cells 1,250; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus (b) Fluid clear; cells 15, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
6	10/21	10/24	Girl, aged 5 years; temperature normal; not ill on admission; 1 day history of mumps; neurologic examination negative	10/23, temperature rose to 102; had slight headache, anorexia, listless; vomited once; temperature normal after 24 hours; symptoms disappeared after 24 hours	Fluid slightly hazy; cells 330; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
GROUP C					
1	11/24	11/29	Boy, aged 6 years; temperature normal; 2 day history of mumps; not ill; neurologic examination negative	No complaints	Fluid clear; cells 15, monocytes predominating; albumin 1 plus; globulin 1 plus, sugar 3 plus
2	12/10	12/11	Youth, aged 17 years; temperature normal; 1 day history of mumps; not ill; neurologic examination negative	No complaints; temperature normal	Fluid clear; cells 15, monocytes predominating; albumin 1 plus; globulin 1 plus, sugar 3 plus
3	12/20 (a) 12/22 (b) 12/28		Boy, aged 5 years; temperature 99; 1 day history of mumps; no complaints; neurologic examination negative	12/28 had rise in temperature to 105; no complaints; physical and neurologic examinations negative; temperature dropped to normal 12/29	(a) Fluid clear; cells 10, monocytes predominating; albumin 1 plus (slight), globulin 1 plus (slight), sugar 3 plus (b) Fluid clear; cells 70; monocytes predominating; albumin 1 plus, globulin 1 plus, sugar 3 plus
4	11/7	11/13	Boy, aged 5 years; temperature 102; 1 day history of mumps; not ill; no complaints; neurologic examination negative	Temperature dropped to 99 11/9, 11/13 rose to 101; no complaints at any time; physical and neurologic examinations negative	Fluid clear; cells 850, 98% monocytes; albumin 1 plus, globulin 1 plus, sugar 3 plus
5	11/29	12/4	Boy, aged 6 years; temperature on admission 101; 1 day history of mumps; not ill; no complaints; neurologic examination negative	Temperature dropped to normal 12/1 and remained normal; no complaints	Fluid clear; cells 25, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus
6	11/8	11/13	Boy, aged 7 years; temperature on admission 101; no complaints; neurologic examination negative	During first 5 days temperature varied from 99 to 100 and then remained normal; had a mild sore throat 11/13	Fluid clear; cells 300, monocytes predominating; culture negative; albumin 1 plus, globulin 1 plus, sugar 3 plus

Normal spinal fluid: Fluid, clear; cells, 0 to 10; smear, negative; culture, negative; albumin, plus-minus (\pm); globulin, plus minus (\pm); sugar, 0 plus.

encephalitis nor would one resort to a lumbar puncture for diagnosis. The symptoms did not last for more than a few hours and were not severe enough to require sedation.

GROUP C

The six cases in group C did not present any sign or symptom clinically which would even suggest the possibility of meningo-encephalitis. They were all symptom free although, in some of the cases, there occurred a slight rise in temperature for from twelve to twenty-four hours.

Examination of the spinal fluid in all these sixteen cases showed an increase in the cell count. The fluids with the higher cell counts were hazy in appearance. The cell counts did not vary with the severity of the disease, since high cell counts were found in some of the milder cases. As a matter of fact, the highest cell count (1,250 cells) occurred in one of the mild cases (group B). All smears showed an increase in cells with a great preponderance of mononuclear cells. The proteins were increased qualitatively in all spinal fluids. Sugar was normal. Spinal fluid cultures were negative. Blood counts, done in all cases, did not show any unusual features. Urinalysis was normal in nearly all cases.

The detailed data of the individual cases are presented in summary in the accompanying tabulation.

COMMENT

There are several phases of the neurologic aspect of mumps which deserve comment. In the first place, the question naturally arises as to the etiology of meningo-encephalitis in mumps. The spinal fluid in these cases was sterile with the ordinary culture methods and when injected into laboratory animals produced no untoward effects. It is generally conceded that the involvement of the central nervous system in mumps is caused by a virus. The mere fact that the virus is not found in the spinal fluid does not negate this conception because in other virus diseases of the central nervous system, such as poliomyelitis and rabies, the virus usually cannot be demonstrated in the spinal fluid, although it is present in the substance of the brain and spinal cord.

Dr. Josephine Neal believes¹ that the mumps virus itself is the cause of the meningo-encephalitis, since the virus of mumps has a tendency to invade tissues other than the parotid gland, and also because the symptoms are less varied than in other forms of encephalitis. However, one may conjecture whether it may not be due to some other virus infection superimposed on a parotitis.

There are two factors to be considered in the apparent increase in involvement of the central nervous system in mumps. First, the diagnosis can undoubtedly be made more often, particularly in mild or symptom-free cases of mumps, by resorting to lumbar punctures more frequently. In addition, Dr. Neal has often stated in her discussions on this subject that the incidence of virus infections of the central nervous system has definitely increased in recent years and that this holds true also for the involvement of the central nervous system in mumps.

As regards the status of the symptom-free group of cases, I suppose one may consider them as subclinical types of infection of the central nervous system. For there undoubtedly must have been some pathologic condition in the meninges or encephalon, or both, to produce the increase in cells and abnormal amounts of protein in the spinal fluids in these cases.

1. Personal communication to the author.

SUMMARY

1. It has been shown that the incidence of meningo-encephalitis in mumps is not as unusual as it was formerly thought to be.

2. Meningo-encephalitis in mumps may occur with very mild symptoms or with no symptoms whatever and, under these circumstances, it could not be diagnosed without a lumbar puncture.

291 Pleasant Valley Way.

JAUNDICE FROM BISMUTH COMPOUNDS USED IN THE THERAPY OF SYPHILIS

REPORT OF THIRTY-TWO CASES

RUBEN NOMLAND, M.D.

IOWA CITY

EDWARD A. SKOLNIK, M.D.

CHICAGO
AND

LAWRENCE L. McLELLAN, M.D.

PHILADELPHIA

Jaundice occurring during the treatment of syphilis has been the subject of a great deal of study. When medication has been thought to be the cause of the jaundice, the arsphenamines have been blamed in almost every instance. Relatively few authorities have suggested that bismuth compounds used in the treatment of syphilis could cause jaundice. Padgett and Moore¹ in their two recent reviews of syphilis did not mention bismuth jaundice. Stokes² in his textbook also omitted mention of bismuth jaundice. There are a few reports of jaundice occurring after treatment with bismuth compounds, but none go into any detail. In Ruge's³ review of more than 700 cases of jaundice in patients under treatment for syphilis he mentioned ten who acquired jaundice and had had only bismuth therapy. Langeron⁴ observed two cases of bismuth jaundice and cited fifteen reports of the condition made to him personally. He concluded that bismuth is not hepatotoxic, as is arsphenamine, but that it has a non-specific action on the liver previously damaged by syphilis, arsphenamine, alcohol or other agent.

Graffar⁵ in his series of 246 cases of jaundice observed seven persons who had received bismuth compounds alone and fourteen more to whom arsphenamine had last been given a year or more previously. He did not discuss the cases of bismuth jaundice. Soffer⁶ recently made an extensive study of arsphenamine jaundice. He had a series of 143 cases in which jaundice developed during treatment. Two of the patients had received only bismuth therapy. He also did not discuss the problem, although he considered the possibility that interval treatment with heavy metal was

a factor in the cases of late jaundice, that is, those in which the condition occurred three months after the last injection of arsphenamine. About one third of his cases were of the late type. Wile and Sams⁷ did not consider bismuth as a cause of jaundice, although all their patients received interim treatment with heavy metal. Presumably this was a bismuth compound, and as almost two thirds of their cases were of the late type, there was probably an adjuvant action of bismuth in their cases of late jaundice.

It is not our intention to discuss the theories of the cause of jaundice occurring during or after treatment of syphilis, because that has been done adequately. It is virtually impossible to differentiate jaundice caused by antisypilitic therapy from so-called catarrhal jaundice, and bismuth jaundice cannot be differentiated from arsphenamine jaundice. The available evidence indicates that syphilis of the liver and the so-called hepatorelapse are unimportant factors in therapeutic jaundice.

In a large outpatient clinic over a period of five years, jaundice attributed to the treatment developed in seventy-five cases. Extensive study of the cases was not possible, but the criteria for diagnosis were lack of evidence of syphilis of the liver and of other disease of the liver or biliary system, development of the jaundice within a reasonable time after the last treatment and complete clinical recovery. For bismuth compounds the time chosen was six weeks and for arsphenamine twelve weeks.

The jaundice observed could be classified in the following categories:

1. Herxheimer's jaundice (hepatorelapse), with the jaundice occurring within one week after the beginning of treatment of early syphilis with arsphenamine, three.
2. Arsphenamine jaundice, eighteen.
3. Bismuth jaundice, thirty-two.
4. Arsphenamine or bismuth jaundice—jaundice developing while the patient was receiving bismuth but within twelve weeks after the last injection of neoarsphenamine, ten.
5. Unclassified but probably therapeutic jaundice, five.
6. Mapharsen jaundice, two.
7. Tryparsamide jaundice, one.
8. Jaundice from mercury; one.
9. Jaundice from sodium cacodylate, one.
10. Fatal jaundice, two.

Because jaundice from bismuth had been largely unrecognized, we felt that study of these cases was most important.

Our criteria for the diagnosis of bismuth jaundice were lack of previous treatment with arsphenamine, at least within the preceding three months; development of jaundice within six weeks after the last treatment with a bismuth compound; absence of other causes of jaundice, and complete clinical recovery.

The patients with bismuth jaundice numbered thirty-two and could be divided into two groups. The first group, numbering ten, had had no arsphenamine. The second group, numbering twenty-two, had had neoarsphenamine but none within twelve weeks before the onset of the jaundice.

In six of the ten patients who had had only bismuth, the jaundice developed within one week after the last treatment; in three it developed in from one to two weeks, and in one it developed in from two to three weeks.

Of these ten patients one had had from one to ten injections of a bismuth compound, four from eleven to twenty injections, three from twenty-one to thirty injections, and two over thirty injections.

The diagnosis in three cases was cardiovascular syphilis and in one case syphilis of the central nervous system. In two cases it was cutaneous, nodular, ulcerative syphilis and in four cases latent syphilis. There were no cases of early syphilis because in these neoarsphenamine was given as a matter of routine.

In all cases the bismuth preparation was bismuth subsalicylate given in a dose of 1.5 or 2 cc. of the ten per cent suspension in oil at weekly intervals.

Age, sex, race and season of the year did not seem to have any bearing on the incidence of the jaundice.

Of the twenty-two patients who had had neoarsphenamine but whose jaundice was presumed to be caused by bismuth, seven had had their last neoarsphenamine from twelve to sixteen weeks before, three from sixteen to twenty-three weeks before, eleven from twenty-four to thirty weeks before and one over thirty weeks before. Because of the time which had elapsed since the last injection of neoarsphenamine, we felt that it had nothing to do with the jaundice.

Jaundice developed in four patients in the first week after the last treatment; in five, within one to two weeks; in three, within two to three weeks; in four, within three to four weeks, and in five, within four to six weeks.

The amount of bismuth given was from eleven to twenty injections in nine cases, from twenty-one to thirty injections in six and thirty-one or more injections in five.

The diagnosis was secondary syphilis in nine cases, latent syphilis in ten cases, cardiovascular syphilis in one case and neurosyphilis in one case.

In all except three the bismuth preparation used was 10 per cent suspension of bismuth subsalicylate in oil given in a dose of 1.5 cc. Three patients received considerable amounts of an aqueous bismuth compound; namely, bismuth potassium tartrate or bismuth sodium tartrate.

In this group there were a considerable number of patients with early syphilis in whom jaundice developed from three to seven months after their last injection of neoarsphenamine, while they were being treated with a bismuth compound. There was nothing significant in the age, sex, race or seasonal incidence of the jaundice.

The clinical picture in bismuth jaundice is in no way distinguishable from that of other forms of toxic jaundice, such as jaundice from neoarsphenamine, from mapharsen, from sodium cacodylate or from other drugs which may cause jaundice. Our experience is like that of others in that we found no way in which jaundice of this type can be differentiated from acute catarrhal jaundice with any degree of certainty except by the history of the giving of the causative drug.

The severity of jaundice from bismuth was variable, but most of the attacks were mild or moderately severe. Probably the best conception can be given by abstracts of typical case histories:

An example of mild jaundice occurred in a woman aged 34, who had late cutaneous syphilis. She noted yellowness of the eyes nine days after her last injection of bismuth subsalicylate. On physical examination nothing was found except mild yellowing of the conjunctivas and bile in the urine, which was dark. Two weeks later there was no evidence of jaundice, and treatment was resumed.

⁷ Wile, U. J., and Sams, W. M.: A Study of Jaundice in Syphilis: Its Relation to Therapy. *Am. J. M. Sc.* 157: 297 (March) 1934.

An example of moderate jaundice occurred in a man who had late latent syphilis treated only with bismuth compounds. He noted yellowness of his eyes about eighteen days after the last treatment and had mild tenderness in the right upper quadrant. Physical examination revealed icterus of the conjunctivas, and bile was found in the urine. The liver was palpable two fingerbreadths down and slightly tender. After three weeks the scleras and the urine were clear and the liver was not palpable. Treatment was resumed, including administration of a bismuth compound, without untoward incident.

An example of the more severe bismuth jaundice occurred in a man aged 51 with latent syphilis, in whom jaundice developed after his fifteenth injection of a bismuth compound. Sixteen days later he noted that his eyes were yellow and that his urine was dark. A few days later he had chilly sensations, was nauseated, belched and had moderately severe abdominal pain. These symptoms lasted only three or four days. When he was examined at this time, about nine days after the onset, his scleras were markedly icteric, his liver was tender and palpable three fingerbreadths below the costal margin. There was much bile in the urine, with albumin and casts. The stools were light in color but not clay colored. The jaundice remained deep for about thirty days and cleared within two weeks, enduring six weeks all told. The stools were light colored only a few days. When the patient was examined after recovery the liver could not be palpated, the urine was normal and there was no after-effect from the jaundice.

Of the ten persons with jaundice who had had only a bismuth compound, two had mild, five moderate and three severe jaundice. Of the twenty-two who had been given arsphenamine twelve or more weeks and a bismuth compound six weeks or less before jaundice developed, nine had mild, ten moderately severe and three severe jaundice.

The incidence of bismuth jaundice over a period of five years has been one attack for 2,242 injections of bismuth compounds. The incidence of jaundice from neoarsphenamine during the same period has been one attack for each 951 injections. We cannot give figures on the percentage of patients affected, but it cannot be much more than 1 per cent of the number who received adequate treatment for their syphilis. In spite of the fact that there were more cases of bismuth jaundice than of neoarsphenamine jaundice, the incidence per injection of neoarsphenamine was over twice as great.

To those who would question the validity of the diagnosis of bismuth jaundice one can say that the same reasoning is involved in diagnosing this type as in diagnosing other therapeutic jaundice. In general the criteria are recent treatment with the suspected drug, absence of any other cause of jaundice, and clinical recovery which, except in rare cases, is complete.

Forms of therapeutic jaundice cannot, in our opinion, be differentiated from each other except on the basis of the history of the drug used. They cannot be differentiated from so-called catarrhal jaundice. In fact, several authors, especially Ruge, maintain that therapeutic jaundice with syphilis is not primarily from the therapy but follows closely the incidence of simple infectious (catarrhal) jaundice.

SUMMARY AND CONCLUSIONS

Seventy-five cases in which jaundice occurred during therapy for syphilis were studied. In thirty-two the cause was thought to be a bismuth compound. In these thirty-two the jaundice began within six weeks after the last treatment. Ten of the patients had had only the bismuth compound. Twenty-two had had neoarsphenamine, but none within twelve weeks of the onset

of the jaundice; in fifteen cases more than fifteen weeks had elapsed since the last treatment with neoarsphenamine. All the patients with bismuth jaundice recovered, and most of them were subsequently given a bismuth compound without its causing harm. In six of the thirty-two the jaundice persisted for six weeks or more.

MESENTERIC VASCULAR OCCLUSION

LORIN D. WHITTAKER, M.D.

Fellow in Surgery, the Mayo Foundation
PEORIA, ILL.

AND

JOHN DEJ. PEMBERTON, M.D.

ROCHESTER, MINN.

Mesenteric vascular occlusion, one of the most fatal of all abdominal catastrophes, arises in a variety of ways and gives rise frequently to bizarre symptoms. This condition most often defies recognition and is treated by various surgical and nonsurgical methods, usually to no avail. Its occurrence is relatively rare and few cases are seen in any one surgical practice. However, in the study of a series of these cases, facts regarding origin and pathogenesis are obtained, predominant symptoms are recognized and types of treatment used may be evaluated, all of which may aid in recognition and management in the occasional case.

The study we are presenting is based on a consecutive series of sixty proved cases seen at the Mayo Clinic, in fifty-seven of which necropsy was performed; in the remaining three cases surgical procedures performed for the occlusion were survived. Cases in which the symptoms and clinical course were suggestive but were not proved by observations at the time of operation or by examination at necropsy were not included in this study.

ETIOLOGY

In this series of sixty patients there were thirty-five males and twenty-five females. The condition was seen most frequently when the patients were at that age in which complications of preexisting disease begin to be manifest, or evidence of degenerative processes begins to appear. The average age of the males was 45 years and the average age of the females was 43 years. The youngest patient was 13 years of age, and the oldest was 83. Mesenteric vascular occlusion in the young was seen more frequently following acute abdominal infections than in relation to any other condition.

There were thirty-six cases (60 per cent) in which mesenteric vascular occlusion was unrelated to any previous surgical procedure and, of this group, only sixteen (44.4 per cent) of the patients were subjected to abdominal exploration; the condition of the remaining twenty patients did not warrant surgical intervention. Of these twenty patients, sixteen were under observation at the clinic for chronic conditions, predominantly cardiac disease (ten cases). In the remaining four cases of the twenty the diagnosis of "acute abdomen" (two cases) and preeclamptic toxemia and cerebral embolus (one case each) had been made elsewhere. Of the sixteen patients subjected to operation several also were under observation at the clinic for various conditions, mostly cardiac disease, at the time the vascular accident occurred. The preoperative clinical diagnoses in these sixteen cases were respectively intestinal obstruction in seven cases, mesenteric thrombosis in

four, abdominal hemorrhage in two (both occurred in women during the second month of pregnancy) and ruptured appendix (present), strangulated hernia (present) and acute condition of the abdomen in one case each.

There were twenty-four cases (40 per cent) in which mesenteric vascular occlusion followed some operative procedure and, of this group, only three patients were subjected to reexploration. The surgical procedures originally carried out in the twenty-one cases in which reexploration was not made included splenectomy for

splenic anemia (seven cases), a biliary or pancreatic surgical procedure (four cases), appendectomy or drainage for acute gangrenous appendicitis (three cases), a gastroduodenal operation (three cases), operation on the transverse colon (two cases), herniorrhaphy (one case) and extraction of a cataract (one case). Reexploration was not made either because of the patient's immediately poor condition, or because it was felt that operation offered no hope for recovery. Of the three cases in which reexploration was carried out, in one the reexploration followed an operation on the biliary tract; a volvulus was released on the fifth postoperative day and recovery followed. Thrombosis of the vessels which supplied 2 feet (70 cm.) of ileum had occurred. In the second case, reexploration followed splenectomy for splenic anemia. Enterostomy was performed on the twenty-seventh postoperative day; the jejunum was found discolored. Venous thrombosis continued to the extent of completely blocking the superior mesenteric and portal veins; death occurred on the twenty-ninth postoperative day. In the third case reexploration followed hysterectomy. On the eighth postoperative day an internal hernia through the transverse mesocolon was reduced; the lower part of the ileum was discolored, and thrombosis of the superior mesenteric artery and vein progressed to the extent of complete involvement. Death occurred on the tenth postoperative day.

The mortality rate in this condition is stated to be from 85 to 100 per cent. As has been said concerning the series under consideration here, in thirty-six cases the occlusion was unrelated and in twenty-four cases it was related to a previous operation. Of the twenty-four patients, as also has been shown, three were operated on again in an attempt to treat the occlusion and one survived. Of the thirty-six patients, sixteen were operated on for the same reason and two survived. These three patients were the only ones in the entire group of sixty who survived. Therefore the mortality rate in this entire group was 95 per cent; the mortality rate of patients operated on for occlusion was 84.2 per cent, since sixteen of nineteen died. However, it is to be remembered that the series does not include the cases in which the diagnosis was not definitely proved, the cases in which the patient may have survived surgical operation and in which a definite diagnosis was not established, or those cases in which the patient may

have suffered mesenteric occlusion and have recovered without surgical intervention for the occlusion. The types of occlusion and the vessels occluded are given in table 1.

The incidence of involvement of the superior mesenteric artery as compared with that of the superior mesenteric vein compares closely with the relative incidence reported by other authors. Involvement of the inferior artery in one case and of the inferior vein in two cases presents a rather high incidence of such involvement.

The source of mesenteric vascular occlusion varies as to whether the artery or the vein is involved. Superior mesenteric arterial occlusion occurs either because of thrombosis or of embolism. Thrombosis was found more often following operation associated with conditions predisposing to thrombosis, such as splenic anemia and severe grades of arteriosclerosis, than when other conditions were present. Embolism was more frequently associated with degenerative heart disease or with acute valvular disease than with other diseases (table 2). Arteriosclerosis accounted for the occurrence of the case of thrombosis of the superior and inferior mesenteric arteries.

Occlusion of the superior mesenteric vein occurs secondary to ascending thrombosis usually attributable to infectious processes, secondary to descending thrombosis from the associated portal vein or secondary to hepatic disease, or it follows an abdominal surgical operation. Hepatic cirrhosis was noted in some cases of splenic anemia and may have been contributory to thrombosis in these cases following splenectomy (table 2).

PATHOLOGY

Vascular occlusion was complete in each case studied. There was associated thrombosis of the portal vein in eighteen cases (30 per cent) and there existed associated pulmonary thrombosis in seven (11.6 per cent). There was one case in which associated thrombosis of the celiac axis had occurred and gangrene of the mucous membrane of the stomach was observed. Also, in a few cases, old organized nonocclusive thrombi were present

in the superior mesenteric vessels, indicating that the patient previously had survived mesenteric thrombosis which was not completely occlusive.

Involvement of the bowel varied in extent from a few inches to include all the small bowel and the right half of the colon. The earliest examinations of the bowel were made from seven to eighteen hours after onset of symptoms and revealed an edematous, congested, deep red or bluish intestinal wall, frequently stretched by distention to a moderate degree and presenting a somewhat granular surface. The mesentery was dark, doughy and thickened as the result of hemorrhage. This is the picture of hemorrhagic infarction of the bowel. Infarction of the bowel is practically always hemorrhagic in

type, as has been shown previously by Dye,¹ Jones² and others. Recovery of the bowel is possible early in this stage, but the process usually proceeds rapidly to a state of gangrene. Accompanying this gangrene is bloody ascites and the bowel usually is distended, not with gas but with fluid blood. The bloody ascites is almost pathognomonic of gangrene and is considered by Warren and Eberhard³ to be probably a transudate from the congested, hemorrhagic, infarcted bowel. The blood within the bowel comes from the gangrenous mucous membrane, that part of the wall of the bowel in which gangrene occurs first in all probability. Considerable blood is lost in this way and manifestly adds considerably to the late shock so frequently seen. Perforation of the bowel was not observed in this series of cases; peritonitis, however, was common, being the end result of the process. Complete gangrene of the bowel with bloody ascites and a blood-filled lumen was seen as early as eighteen hours following onset of symptoms. Rapid progression of the pathologic changes is illustrated by the case of a man aged 54 who had myocardial degeneration and auricular fibrillation. Exploration nine hours after onset of symptoms revealed a dark, edematous jejunum, the changes extending down into the ileum, and necropsy twenty-four hours after onset of symptoms revealed gangrene of the jejunum and of the upper three fourths of the ileum, with bloody ascites and bloodfilled bowel lumen. An embolus of the superior mesenteric artery was present.

Venous thrombosis may start in the fine venous radicles adjacent to the bowel or may originate in the portal vein, but progression of thrombosis is the rule in either the ascending or descending types. Progression of changes in the bowel following venous occlusion is usually not as rapid as that following arterial occlusion.

Recovery probably occurs spontaneously in some cases in which the condition does not proceed beyond an early stage of hemorrhagic infarction. Likewise, recovery may follow complete occlusion of the mesenteric artery by embolism or thrombosis. Dye collected three reports of cases in which recovery from a typical attack occurred, the patients later dying of other causes and, at necropsy, an obliterated superior mesenteric artery being found. Collateral circulation may be established. We have one similar case in our series. A man aged 42 had experienced several previous operations on the upper part of the abdomen. Following drainage of an abscess of the abdominal wall caused by perforation of the jejunum, pyelophlebitis of the superior mesenteric vein and portal system developed, with abscesses of the liver, and he died. Necropsy revealed the superior mesenteric artery completely occluded by an organized thrombus. Collateral circulation had been established through the inferior mesenteric and gastric arteries. The intestine appeared normal.

SYMPTOMS AND DIAGNOSIS

One definite symptom complex of mesenteric vascular occlusion cannot be recorded, for there exists a wide variation in the extent of pathologic changes and in the mode of onset. Only a few inches of bowel may be involved, or gangrene of the whole of the small bowel and even of part of the colon may be present. Also there may occur a sudden, prostrating arterial occlusion or a more slowly progressive venous occlusion.

The presenting symptoms are those of an acute abdominal emergency. There are, however, a few symptoms which, if present, are suggestive of mesenteric occlusion. Pain was the most common symptom in our series and occurred in practically every case. When arterial occlusion was present, the pain was described as being sudden, severe and more frequently generalized than localized to the epigastrium. The pain in cases of combined arterial and venous occlusion was similar to that accompanying arterial occlusion, although occasionally it was described as a generalized, dull, cramping pain. Venous occlusion frequently gave rise less suddenly to pain, but the pain was severe and more often generalized than localized to the epigastrium. However, the severe pain of venous occlusion was preceded in a few cases for varying periods of time by a less severe, dull, aching pain. In all three types the pain was more frequently constant than intermittent or cramping in nature.

Vomiting was the next most frequent symptom. It occurred in about 75 per cent of the cases of arterial and combined arterial and venous occlusion and in 50 per cent of the cases of venous occlusion. Vomiting at first was of reflex type and was productive of gastric

content only; vomiting was somewhat protracted and the vomitus was contaminated with blood in only three cases (5 per cent).

Distention occurred in twenty-nine cases (48.3 per cent); it was considerably more common in the presence of venous occlusion than in that of arterial, or combined arterial and venous occlusion. It usually was of only moderate degree. When the thirty-three cases of arterial and combined arterial and venous occlusion are considered, signs were as follows: The abdomen was described as rigid in seven (21 per cent) and tender in five (15 per cent). The abdomen was tender in only one case of venous thrombosis, and rigidity was not noted in the presence of venous thrombosis.

Constipation was noted much more frequently than diarrhea. Blood was noted most often in the cases of venous thrombosis, either in the stool spontaneously evacuated or following an enema; this occurred in ten of the twenty-seven cases of venous thrombosis, or 37 per cent. When the thirty-three cases of arterial or combined arterial and venous thrombosis are considered, blood was noted in only four cases (12 per cent), making a total of fourteen in the series of sixty cases, an incidence of 23 per cent. Although blood was noted in only 23 per cent of the sixty cases, its presence in the stool spontaneously or following an enema is a valuable diagnostic sign.

Shock was noted in nine of the nineteen cases (47 per cent) of arterial occlusion and in five of the fourteen cases (36 per cent) of combined arterial and venous occlusion but in only two of the twenty-seven cases (7 per cent) of venous thrombosis.

The number of leukocytes was higher than that usually associated with occurrence of other abdominal

2. Jones, H. W.: Recurring Mesenteric Thrombosis, *Am. J. Surg.* 22: 318-320 (Nov.) 1933.
3. Warren, Shields, and Eberhard, T. P.: Mesenteric Venous Thrombosis, *Surg., Gynec. & Obst.* 61: 102-121 (July) 1935.

emergencies. The higher values were associated with arterial occlusion, rising rapidly and reaching as high as 35,000 per cubic millimeter of blood within eight hours after the onset of symptoms. The average number of leukocytes recorded in cases of arterial occlusion was 27,000. In cases of combined arterial and venous occlusion the average number was 22,000. In the presence of venous occlusion the range of the number of leukocytes was more variable; the average number was 20,000.

It is probably of academic interest only to discuss points of differential diagnosis between arterial and venous occlusion, for retrograde venous occlusion may follow arterial occlusion and likewise, when venous circulation is blocked, arterial circulation may eventually become occluded. However, discussion of symptoms may help perhaps in recognition of mesenteric vascular occlusion. Pain was severe in the presence of both types of occlusion, more frequently sudden and prostrating in the presence of arterial occlusion, more frequently progressively severe in the presence of venous occlusion. Vomiting was more frequently associated with arterial occlusion, accompanying the severe, sudden attacks of pain. The abdomen in the presence of arterial occlusion was more frequently rigid and tender but much less frequently distended than when venous occlusion was present. Constipation was common to the two but bleeding from the rectum was decidedly more frequent in the cases of venous occlusion. Shock was infrequent when primary venous thrombosis occurred and was frequent when arterial occlusion was present. The number of leukocytes was elevated more consistently and to higher levels in the presence of arterial occlusion than when venous occlusion was present. The usual course of the disease following onset of symptoms varied from eighteen hours to three days; it was probably somewhat more rapid in cases of arterial occlusion.

PROGNOSIS AND TREATMENT

The prognosis of mesenteric vascular occlusion, even when recognized and treated very early, is extremely poor. The poor condition of the patient soon after onset of the condition often precludes surgical intervention and, if the patient is operated on, occlusion and involvement of the bowel are frequently so extensive that resection of the involved portion cannot be carried out with any hope for survival of the patient. Finally, thrombosis may continue to extend after excision of the originally involved segment of the bowel and of mesentery has been accomplished.

In most of the cases of our series the entire small bowel was beyond restitution, even though exploration was carried out as early as nine hours after onset of symptoms. Table 3 indicates the procedures resorted to. Of the three cases in which recovery occurred, resection of the involved portion was carried out in one, release of volvulus was effected in another, and a Mikulicz type of extraperitoneal resection of the involved segment of bowel was performed in the third. These three patients had less extensive involvement than the others. It seems that no one surgical procedure is best and any sound operative procedure in surgery of the bowel is applicable. The extensiveness of the disease, the tendency for thrombosis to progress or to recur following operation and the results of gangrene, namely, hemorrhage and peritonitis, make for the universally high mortality.

SUMMARY AND CONCLUSIONS

In this series of sixty proved cases of mesenteric vascular occlusion, in thirty-six (60 per cent) the condition was unrelated to any surgical procedure and in twenty-four (40 per cent) it occurred following some surgical procedure. Surgical measures were resorted to in treatment of the occlusion in only nineteen cases (31 per cent) with a mortality rate of 84 per cent. The condition of the forty-one remaining patients precluded any hope of surgical intervention. Arterial occlusion occurred in nineteen cases (31.7 per cent), venous occlusion in twenty-seven cases (45 per cent) and combined arterial and venous occlusion in fourteen cases (23 per cent). Cardiac disease, hepatic or splenic disease, arteriosclerosis and acute abdominal infections were the predominant factors in the etiology of mesenteric vascular occlusion.

The symptoms were those of an abdominal emergency. Pain was the most common symptom and was more sudden and severe in arterial occlusion. Vomiting was frequent. Rigidity and tenderness were more common with arterial occlusion, while distention alone was more suggestive of venous occlusion. Bleeding from the bowel occurred decidedly more frequently in the cases of venous occlusion but occurred in only fourteen cases (23 per cent) of the series; it is a valuable diagnostic sign if present. The leukocyte count was elevated to higher levels than that usually encountered in the more frequent abdominal emergencies. The rapidity of progress, the extensiveness of the disease and the tendency for progression or recurrence following operation make for poor prognosis.

Clinical Notes, Suggestions and New Instruments

AN UNUSUAL SHOWER OF FUNGUS SPORES

O. C. DURHAM, NORTH CHICAGO, ILL.

A striking instance of atmospheric transport of vegetable allergens is afforded by the figures for the incidence of *Alternaria* and *Hormodendrum* spores on October 6 and 7 throughout the eastern part of the United States. Weather bureau records show that on these two days air masses from the Northwest at elevations of from 2,000 to 6,000 feet moved rapidly southeastward and eastward, covering the distance from Minnesota to the Atlantic seaboard and the gulf in about fifty-five hours. During this time thousands of tons of mold spores were transported an average distance of several hundred miles. At nearly every station on and east of the Mississippi River where records were taken the catch of *Alternaria* spores during one or the other of the two days of the storm exceeded that found on any other day during the entire summer and fall. Figures were particularly high in Minneapolis, St. Louis, Memphis, Indianapolis, Buffalo and Cleveland, but an acute rise in the spore count was found as far east as New York and Washington, D. C., and as far south as New Orleans. The intensity of the storm can be best appreciated by a comparison of the slide counts for the day of the storm and the average figure for October. At seventeen stations the average increase in the *Alternaria* spore count during the storm was 100 times that of the mean daily count for the month of October (exclusive of the day of the storm). In the tier of states from Texas to North Dakota the wave of fungus spores was noticeable but not so striking as in the area previously mentioned.

The point of origin of the atmospheric load is somewhat uncertain, but quite likely it was in southern Minnesota. At Minneapolis the deposit on the slide probably occurred early

on the morning of October 6. By the next morning at 8 o'clock the effect had been felt as far east as New York City and as far south as Oklahoma City. During the day and the following night the storm reached Dallas, Memphis, Nashville, Atlanta, Washington, D. C., and New Orleans. It is unlikely that these spores originated locally in each area, because the velocity of surface winds on the dates given was not unusually high. Moreover, it is difficult to believe that a crop of mold spores could have matured in such unusual quantities simultaneously in so large an area.

The figures show the total *Alternaria* spore count at the various stations on the day of the maximum deposit of these spores during the storm described. The area counted was 1.8 sq. cm. on a petrolatum-coated slide exposed for a twenty-four hour period.

The phenomenon was doubtless due to the transport of mold spores by large air masses rather than by the temporary agitation of locally produced spores. In my ten year study of the behavior of atmospheric pollen I have not observed a transfer of allergen particles so striking in amount or over such a widespread area.

Such a shower of allergen particles can easily account for a sudden exacerbation of hay fever symptoms. A brief inquiry has disclosed the correlation of clinical symptoms with the advent of this storm in some of the places affected.

Abbott Laboratories.

DERMATITIS CAUSED BY DIETHYLENE GLYCOL IN TOBACCO

BEN A. NEWMAN, M.D., LOS ANGELES

P. H., a white man, aged 39, an aviator, complained of a dermatitis of the left index and middle fingers of six weeks' duration and of the left upper lip of four weeks' duration. Two months before, he had been in a hospital for a period of six months because of fracture and amputation of one thigh. He stated that there was no personal or family history of allergy. The eruption was pruritic. It consisted of pinpoint to pinhead size vesicular and scaling lesions on an erythematous base. The borders were ill defined and gradually faded into the normal skin. Wet dressings of solution of aluminum acetate were prescribed for two days, and this was followed by a single fractional dose of superficial x-ray irradiation and zinc ointment U. S. P. Two weeks later the eruption on the fingers was greatly improved but that on the lip remained unchanged. In the meantime an identical eruption had developed on the same fingers of the other hand. Since the patient was an inveterate cigaret smoker and the location of the lesions was the site of direct contact with the cigaret, patch tests were done with the suspected agents. He was tested with the tobacco and paper of the three brands of cigaretts he had been in the habit of smoking. A reaction, i.e., vesiculation, was obtained to the tobacco of one brand after forty-eight hours of contact. This was the cigaret containing diethylene glycol and the brand which the patient had started to use only from two to four weeks before the onset of the dermatitis. A subsequent patch test was done with a 5 per cent aqueous solution of diethylene

glycol; this test was also applied to two other persons as controls. After twenty-four hours of contact, only the patient showed a positive reaction.

The eruption on the right hand appeared when the patient had shifted the cigaret to those fingers after dressings and bandages were applied to the fingers originally involved. Two weeks after he stopped using this brand of cigaret the patient was entirely well.

SUMMARY

In the case reported, contact dermatitis proved to be caused by diethylene glycol.

3875 Wilshire Boulevard.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

ACOUSTICON HEARING AIDS (CORONATION MODELS) ACCEPTABLE

Manufacturer: Dictograph Products Company, 580 Fifth Avenue, New York.

Three Coronation Models of Acousticon Hearing Aids, each instrument consisting of a carbon ball type microphone transmitter, a plug-in style carbon-particle type amplifier, a current-varying rheostat, a plug-in type air conduction midget receiver or, interchangeably, a bone conduction type oscillator, and the usual connecting cords and batteries, were examined by the Council. The bone conduction oscillators, the air conduction receivers and the carbon particle amplifiers were each supplied in three nominal frequency ranges, low, intermediate and high; each one of the three Coronation Model hearing aids could be combined with any of the component parts selected at will within the three frequency ranges.

MODEL C-2.—The distinguishing feature of this model is a carbon ball type microphone transmitter, housed in a metal case measuring $2\frac{1}{4}$ inches across the face and about one-half inch thick. It is finished in lacquered gold on the front perforated face, with a clip on the rear for fastening the microphone to the clothes. A further feature of this model is a separate current-varying rheostat about the shape and size of an average fountain pen cap, also furnished with a spring clip for fastening to the clothes. As already mentioned, the plugs and jacks which terminate the cords furnished may be used to place in circuit any pieces from a threefold selection of

Fig. 1.—Relative response of Coronation Model air conduction midget receivers only.

amplifiers, air conduction receivers having interchangeable form fitting ear pieces or bone conduction oscillators held in place with a spring band, and plug-in type batteries in either 3 or $4\frac{1}{2}$ volt size.

MODEL C-4.—This model is distinguished by a carbon ball type microphone transmitter housed in a molded bakelite case, measuring $3\frac{1}{4}$ inches across by $\frac{1}{2}$ inch thick, with a semi-

circular projection at one side carrying a rheostat. The front face of the microphone case is perforated in the central region by a number of holes forming together a symmetric pattern. On the back of the case is a spring fastening clip.

Model C-6.—This model appears externally to be identical with Model C-4, differing only in that in the front face of the microphone case are indentations for a series of holes near the outer periphery. These are outlined but not punched out as in the Model C-4. In addition, near the center are three small holes about one thirty-second inch in diameter.

All the instruments and components are apparently well constructed and finished. The plugs, bone conduction oscillators and amplifiers are shaped so as to be free from sharp corners and so as to fit together smoothly.

Test Method.—Because of the large number of combinations possible with each of the models and because of the various interchangeable components, it was decided to limit the final and decisive intelligibility, articulation and gain tests to that combination of parts which was best suited to normal human hearing. Accordingly the frequency-response characteristics of the various components were determined separately. The air conduction receivers and the bone conduction receivers, because of the nature of their construction, appear to be stable in their performance. The data obtained may be used to predict what results will be achieved when these parts are used in combination with other components. Figure 1 shows the relative response obtained by using an artificial ear for testing the air

weeks, in which eighteen male and seventeen female observers were used both as listeners and as readers. Battery voltages were not allowed to diminish with time but were kept up to the full value furnished by new batteries of large capacity. The gain in intensity shown in the last column of the table should therefore be regarded as the maximum gain obtainable, on the average, by the use of full strength batteries.

It will be seen that the sentence intelligibility is relatively high for all models and for all conditions of use, tending to diminish moderately, however, as the volume is increased through the use of high voltage and larger rheostat currents. Syllable articulation shows the same trend. While the intensity gain is not extremely large even for the highest setting, the fact that the intelligibility keeps to a high value is a good indication that the intensity gain is largely a real loudness gain of usable speech sounds, and not mere noise. It was also directly observed by an overall continuously variable single frequency run that the combination of parts here used was comparatively free from large amplification peaks and noisy admixtures.

Fig. 3.—Aurogauge used for fitting hearing aids.

Bone Conduction Tests.—The three hearing aid models were also tested by using the intermediate frequency bone conduction oscillator, marked with a single white dot by the manufacturer. Only sentence intelligibility tests were performed, since no method of rating the loudness gain has as yet been defined. The results, while not as clearly consistent as for the air condition receivers, nevertheless, gave values comparable to those shown in the table. Also when a 4½ volt battery was used and with the rheostat turned full on, the ears being stopped by wide mouthed jars, there is a distinct and marked acoustic transmission and a hearing gain over that obtained by direct transmission of air borne sounds through the head.

Conclusions.—It is concluded that all three Coronation Models, C-2, C-4 and C-6, when used with the components stated, give satisfactory results both for air and for bone conduction as regards sentence intelligibility, syllable articulation and loudness gain. When used with other combinations of components, the performance cannot be predicted but must be uniquely determined for each individual. Apparently the instruments have been carefully designed, and intelligibility has not been sacrificed for an apparent high gain in loudness. The batteries furnished, namely, manufacture numbers 9 and 7, being 3 and 4½ volts battery respectively, also give evidence of careful construction.

In view of the foregoing report the Council on Physical Therapy voted to include the three models, C-2, C-4 and C-6, of the Coronation Acousticon Hearing Aids in its list of accepted apparatus.

AMPLIFYING STETHOSCOPE (MARBEL) ACCEPTABLE

Manufacturer: Marbel Blood Calculator Company, 3267 South Halsted Street, Chicago.

The Amplifying Stethoscope (Marbel) is designed to make audible heart sounds throughout a room or adjoining rooms by means of a loud speaker. The outfit consists of an amplifier, a microphone and a loud speaker. Twenty feet of wire allows the operator to locate the speaker in a convenient place.

This electrical stethoscope enables physicians to hear any irregularities of the amplified heart sounds of patients under surgical anesthesia, and of the mother or the fetus during pregnancy or early stages of labor. It may be used for mass stethoscopic examinations of recruits, factory workers and students.

In order to reach the right amount of amplification, it is advisable for the physician to place the stethoscope-microphone over his own heart and turn the adjusting knobs until the audible sounds are clear. By turning the knobs, the sounds may be made weaker or louder. Care should be exercised in placing the loud speaker, since the microphone and amplifier are highly sensitive and regenerated electrical oscillations may

* All models equipped with air conduction receiver 0 and carbon microphone 3.

conduction receivers as designated by the Dictograph Products Company, numbers 0, 1 and 2. As will be seen from the curves, receiver 0 has the most nearly uniform response characteristic of the three and is the only one which has a considerable output above 3,500 cycles per second. Accordingly, in the final intelligibility tests, only receiver 0 was used.

Similar data, not included in this report, were obtained for the carbon particle amplifiers and revealed that amplifier 3 had the most nearly uniform response characteristic. Moreover, it was verified that the combination of receiver 0 and amplifier 3 gave the highest value of sentence intelligibility with any of the three models of microphone transmitters.

It is possible that for a person having a hearing loss which varies in a complementary way over the acoustic frequency scale a combination of a different numbered receiver and amplifier would give better overall results for that individual.

But when persons with normal hearing are used as observers, the combination stated is the one yielding the most favorable results. Moreover, there is no logical possibility of comparing results so obtained with those obtained from experimentation with persons suffering from hearing defects.

Summary of Results.—Since the three hearing aid models are interchangeable with respect to their other components, the results obtained may be compared when exhibited in tabular form as shown in the table. The tabular values are averages of a great number of separate tests, extending over several

Fig. 2.—Acousticon Hearing Aid, Coronation Model.

build up and produce a high squealing sound. If the loud speaker is moved away, the oscillations are not built up so readily. The microphone may be attached with two pieces of adhesive tape to the patient's chest for heart and lungs, to the abdomen of the lying-in patient for the fetal heart, to the arm for blood pressure sounds, or to the bowel for borborygmi above the point of bowel obstruction. Experience is required by the operator to interpret pathologic conditions of the heart.

Investigated in a clinic acceptable to the Council, this stethoscope gave satisfactory service for listening to the heart beats and also amplifying fetal heart sounds before and during the first stages of labor. During the later stages it was not as satisfactory, since difficulty was experienced in keeping the microphone in place.

In view of the foregoing report, the Council voted to accept the Amplifying Stethoscope (Marbel) for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

NONPROPRIETARY SYNONYM FOR BENZEDRINE AND BENZEDRINE SULFATE

Smith, Kline & French Laboratories inquired concerning the adoption of a descriptive synonym for their trademark, "Benzedrine," since many different terms are being used. At the suggestion of the Council, the firm agreed to adopt the term "alpha methylphenethylamine" as the descriptive chemical name for the substance introduced in therapeutics as Benzedrine. Subsequently, the firm wrote that it understood that when the chemical name is unwieldy a shorter generic name should also be recognized, and suggested "alphametamine" as the coined generic name for alpha methylphenethylamine. The Committee on Nomenclature preferred "amphetamine" to avoid possible misinterpretations of the firm's term. In reply to this suggestion the firm wrote:

"This name [amphetamine] is entirely acceptable to us and we feel that there will be no confusion with any existing names or trade marks."

The Council therefore adopted the name "Amphetamine" as the nonproprietary synonym for Benzedrine, and "Amphetamine Sulfate" as the synonym for Benzedrine Sulfate.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH, Secretary.

BENZEDRINE SULFATE.—Amphetamine sulfate.—Racemic desoxy-norephedrine sulfate.—Racemic benzyl-methyl carbinamine sulfate.— $[\text{C}_6\text{H}_5\cdot\text{CH}_2\cdot\text{CH}(\text{NH}_2)\cdot\text{CH}_2]_2\cdot\text{H}_2\text{SO}_4$.

Actions and Uses.—Benzedrine sulfate is useful in the treatment of narcolepsy, for controlling symptoms similar to those of narcolepsy in the treatment of postencephalitic parkinsonism, in the treatment of certain depressive psychopathic conditions as indicated below and for facilitating roentgenographic studies of the gastrointestinal tract.

Its use is not recommended in the treatment of sleepiness and fatigue in normal individuals because of the possible danger of pressor effects from continued use, because of the dangers of eliminating the warning signal of sleepiness in individuals who are overdoing, because of the possibility of habit formation or addiction from such use and because cases of collapse have ensued when the drug has been used for this purpose. Its use is not recommended for developing a sense of increased energy or capacity for work, or a feeling of exhilaration or as a "pick-me-up" in individuals other than those under the strict supervision of the physician. Its use in depressive psychopathic

cases should be confined to patients in institutions, since the dangers involved in the use of the drug for this purpose in those going about their daily tasks are similar to the dangers mentioned in connection with fighting off sleep. It has been used in the treatment of spastic colitis and pyloric spasm and in many other clinical conditions not mentioned above, but its use for these purposes is not recommended at present.

The very nature of the therapeutic effects, as well as the side actions of this drug, requires that its use be promoted with proper caution as to pressor effect, hyperexcitability, gastrointestinal disturbance, restlessness, sleeplessness and in over-dosage, chills, collapse and syncope. It should also be carefully noted that the drug is contraindicated in cardiovascular disease, especially when hypertension is a sequence of that disease.

Dosage.—The use of this drug should be instituted with a dose of 10 mg. and increased gradually to 40 mg., depending on the amount needed for therapeutic effect and on the condition in which it is employed. In certain cases it may be necessary to repeat the use of the drug three times daily, but it is recommended that such a dosage not exceed 10 to 20 mg. It is preferable, if possible, to administer the effective quantity of this drug during the morning, to avoid interference with sleep.

Manufactured by Smith, Kline & French Laboratories, Philadelphia, Pa. U. S. patent 1,921,424 (Aug. 8, 1933; expires 1950) 1,879,003 (Sept. 27, 1932; expires 1949) and 2,015,408 (Sept. 24, 1935; expires 1952). U. S. trademark 272,377.

Benzedrine Sulfate Tablets: Each tablet contains benzedrine sulfate, 10 mg. (0.01 Gm.).

Benzedrine sulfate occurs as a white, odorless powder; freely soluble in water, slightly soluble in alcohol; insoluble in ether. Its aqueous solution is neutral to litmus. Benzedrine sulfate melts at over 300 C.

Place 1 Gm. of benzedrine sulfate in an Erlenmeyer flask, add 50 cc. of water and 5 cc. of 40 per cent sodium hydroxide solution; then add benzoyl chloride, 0.5 cc. at a time; shake the flask after each addition; add the benzoyl chloride until no more precipitate forms after an addition; recrystallize twice from 50 per cent alcohol solution, dry the crystals; the melting point is 134-135 C.; the nitrogen content of the benzoyl derivative by the micro Dumas method is not less than 5.70 per cent nor more than 5.95 per cent.

Dry about 0.5 Gm. of benzedrine sulfate, accurately weighed, to constant weight at 100 C.; the loss does not exceed 1 per cent. Incinerate about 0.5 Gm. of benzedrine sulfate, accurately weighed; the residue is not more than 0.1 per cent.

Transfer 0.3 Gm. of benzedrine sulfate, accurately weighed, to a beaker and dissolve in 200 cc. of water and 2 cc. of normal hydrochloric acid. Boil and add 10 cc. of boiling 1 per cent barium chloride solution. Allow to stand overnight, filter, wash until free from chloride, ignite at low red heat to constant weight, cool, and weigh; the sulfate content is not less than 25.5 per cent nor more than 26.4 per cent.

Dissolve 0.25 Gm. of benzedrine sulfate, accurately weighed, in 25 cc. of water in a separatory funnel. Add 3 cc. of 10 per cent of sodium hydroxide solution and extract with six 15 cc. portions of ether. Filter the ether extracts into a glass stoppered flask and shake with 20 cc. of tenth-normal hydrochloric acid. Evaporate the ether on a steam bath; add one drop of methyl red solution and titrate the excess acid with tenth-normal sodium hydroxide solution; the benzyl-methyl-carbinamine content is not less than 72 per cent nor more than 73.5 per cent.

NICOTINIC ACID.—3:Pyridine Carboxylic Acid.— $\text{C}_6\text{H}_4\text{O}_2\text{N}$.

Actions and Uses.—Nicotinic acid is accepted for purposes of standardization and clinical experimentation on its use in pellagra.

Dosage.—Experimentally, 0.5 Gm. in five 0.1 Gm. doses daily.

Nicotinic Acid (3:Pyridine Carboxylic Acid)—SMA Co.—A brand of nicotinic acid-N. N. R.

Manufactured by the S. M. A. Corporation, Cleveland. No U. S. patent or trademark.

Vials Nicotinic Acid-Smaco, 5 cc.: Each vial contains 30 mg. of nicotinic acid in sterile physiologic solution of sodium chloride.

Vials Nicotinic Acid-Smaco, 10 cc.: Each vial contains 10 mg. of nicotinic acid in physiologic solution of sodium chloride.

Tablets Nicotinic Acid-Smaco, 20 mg.

Tablets Nicotinic Acid-Smaco, 100 mg.

Nicotinic acid occurs as white, odorless crystals; 0.7 Gm. dissolves in 100 cc. of water at 25 C.; readily soluble in hot water and alcohol, difficultly soluble in ether. An aqueous solution is faintly acid to congo red. The melting point (microscopic melting point apparatus) is 235 C. (rate of heating, 4 degrees in one minute).

Dissolve about 0.05 Gm. of nicotinic acid in 5 cc. of hot water, add 0.05 Gm. of flavianic acid, evaporate carefully to dryness and take up with 5 cc. of cold water; centrifuge the mixture and wash the precipitate three times with 2.5 cc. portions of cold water; recrystallize the solid from 5 cc. of hot alcohol; centrifuge and wash the crystals twice with 3 cc. portions of ether, filter and dry the crystals; the melting point is found to be 249-250 C. (microscopic heating stage-heating time 30 degrees in one minute), $\alpha = -1.498$.

Dissolve 0.05 Gm. of nicotinic acid in 25 cc. of distilled water, add 2.5 cc. of copper sulfate solution 10 per cent; gradually a dark blue precipitate of copper nicotinate forms. Transfer 0.05 Gm., accurately weighed, to a small platinum dish and incinerate; during the charring, a strong odor of pyridine is evolved; the ash is negligible. The U. S. P. XI test for halogens is negative. Transfer 0.1 Gm. to a vessel and dry for five hours, at reduced pressure 2 mm. of mercury in an Abderhalden dryer at 80 C. over phosphorus pentoxide; moisture content should not be more than 0.1 per cent.

Transfer about 0.05 Gm. of nicotinic acid, accurately weighed, to a beaker. Add 20 cc. of boiled distilled water and titrate with 0.1 normal sodium hydroxide, using phenolphthalein as indicator; the alkali used is equivalent to not less than 99.0 per cent nor more than 101.0 per cent nicotinic acid; one cc. 0.1 normal sodium hydroxide is equivalent to 0.0123 Gm.

SATURDAY, JULY 2, 1938

THE SAN FRANCISCO SESSION

More than 6,000 physicians registered their attendance at the San Francisco session, making this the largest meeting of physicians ever held on the Pacific Coast. Noteworthy features of the meeting were the message of Miss Josephine Roche announcing the National Health Conference, to be held in Washington July 18-20, and the reply of the House of Delegates to that message (see pages 52 and 56), the numerous resolutions concerning the relations of physicians to hospitals and to the public, and the Scientific Exhibit. This exhibit has come to be recognized as a week of opportunities for graduate education not equaled by any similar opportunity available to the medical profession.

Contrary to the expectations of agitators who endeavored to incite disharmony and revolt among the physicians who represent the medical profession in the House of Delegates, the House displayed a singleness of purpose and soundness of attitude in its concern with the important questions which came before it. The fundamental principles adopted at Cleveland were reiterated as basic to a high quality of medical service. The importance of economic factors in a solution of the health problem was emphasized. The importance of education of the public, using all the available means for reaching great numbers of people, was again recognized and the work of the headquarters office toward that end was unanimously approved.

In the scientific sections the attendance was frequently beyond the capacity of even the large halls which had been assigned to them. Moreover, many of the topics which have been in the forefront of medical consideration during the past year were exhaustively considered, including particularly blood dyscrasias, industrial diseases, and new methods in the treatment of psychiatric conditions.

Exhibitors in the Technical Exhibit expressed great satisfaction in the attendance and also in the newness of the audience which they were enabled to reach. This audience included great numbers of physicians from the Pacific Coast and Far Western states who do not

frequently have opportunity to attend an annual session of the American Medical Association, with all the varied opportunities for medical advancement that such a session offers.

The medical profession of San Francisco and particularly the officials who were concerned with the arrangements for the annual session deserve the appreciation of all the members of the Association for the efficiency with which they worked. Particularly must credit be given to Dr. Howard Morrow, elected Vice President of the Association, as chairman of the Local Committee on Arrangements. For a year he had been working on the plans for this session. An unfortunate illness made it impossible for him to participate in any of the activities of the week of the annual meeting, but even while incapacitated in bed he kept constantly in touch with the various affairs, ably assisted by two physicians, Dr. Junius B. Harris and Dr. J. C. Geiger, who took care of the details for him.

The many visitors to the annual session, including members of the House of Delegates, expressed almost unanimous satisfaction with the San Francisco session as the most successful medical meeting ever held on the Pacific Coast.

RELATIONSHIP OF VITAMINS TO ENZYMES

The progressive development of knowledge regarding the chemistry and physiology of naturally occurring organic compounds invariably results in an increasing number of demonstrable integrations of the vast body of accumulating information. The final picture thus evolved often provides unexpected chapters in the story of the chemistry of certain of the fundamental processes in the organism. Among the most interesting examples of this situation have been the relationships between certain vitamins of the so-called B complex and some enzymes of prime importance in metabolism.

Several of the enzymes which are concerned in the oxidation and reduction reactions of the cell are conjugated proteins in which the conjugating or prosthetic groups contain one of the vitamins of the B complex. In each of these cases the vitamin, or a molecule of which the vitamin is a part, has been coupled with a protein carrier and the combination exhibits either enzymatic activity or, in certain instances, may be a member of a system which is necessary for the activation of an important enzyme. The three vitamins which are known to exhibit this relationship to enzymes are all members of the B complex. One of these, riboflavin, is a member of the flavin system,¹ an important oxidative chain in the organism. In the flavin system there is present as one member a flavin-containing enzyme which, chemically, is a protein bearer to which is coupled riboflavin phosphoric acid. As another example of the relationship of vitamins to enzymes, one may cite

1. The more recent developments are given in the Annual Review of Biochemistry 6: 335, 1937.

cozymase, which has a fundamentally important part in fermentation, glycolysis and respiration. This coenzyme contains nicotinic acid amide as a component of its chemical configuration.¹ The significance of the latter compound has been increased by the demonstration that it is probably identical with the pellagra preventive factor;² the latter is a member of the vitamin B complex. As a portion of the cozymase molecule, nicotinic acid amide becomes an essential link in the chain of catalysts involved in certain biologic oxidations and reductions. A third example of the role of vitamins in enzyme activity is the association of thiamin with pyrophosphoric acid as a component of an important enzyme system. It has been identified as cocarboxylase, or the coenzyme of carboxylase, the enzyme which appears to be responsible for promoting the anaerobic breakdown of pyruvic acid in mammalian tissue.

Mutual benefits have been derived from the simultaneous expansion of knowledge in the fields of enzymes and of vitamins. The information available regarding the chemical constitution of certain members of the vitamin B complex has greatly facilitated the elucidation of the chemical nature of the prosthetic groups of the flavin enzyme and of cocarboxylase. However, the demonstration that certain vitamins are, chemically, components of biologically important enzymes permits conclusions about the reasons for the indispensability of these vitamins and a demonstration of some of their physiologic functions. It becomes less difficult to explain the requirement of the body for certain dietary components when the latter may be assigned roles as fundamentally important as those relating to the oxidations and reductions which promote the life of the cells.

Current Comment

IN HONOR OF LUDVIG HEKTOEN

The issue of the *Archives of Pathology* for July 1938 is a special number dedicated to Dr. Ludvig Hektoen, editor of the *Archives of Pathology* since its inception in 1926, on the occasion of his seventy-fifth birthday, July 2, 1938. The number includes more than fifty contributions, with a total of 448 pages, all of these contributions being written by former assistants or associates of Dr. Hektoen in his many activities. As a Fellow of the American Medical Association, Dr. Hektoen has been especially active as chairman of the Committee on Scientific Research and as chairman of the Committee on Awards of the Scientific Exhibit. He is widely known as a contributor to the literature of medicine, with 307 items listed in his bibliography. His research on antibodies, on fungi, on iso-agglutination and on infectious diseases is recognized throughout the world. Although many men at 75 years of age

are content to rest in modest retirement, this seventy-fifth anniversary of Dr. Hektoen's birthday finds him at the peak of a great career as executive director of the National Advisory Cancer Council, under the National Institute of Health. THE JOURNAL tenders him on this occasion the congratulations of the medical profession on his birthday, and best wishes for continued health and many more years of distinguished service.

SMALLPOX IN THE UNITED STATES

According to the statistical bulletin of the Metropolitan Life Insurance Company,¹ the year 1937 witnessed another rise in the incidence of smallpox throughout the greater part of the United States. Reports received during the year indicated 11,806 cases as against 7,044 in 1936. Although the form of the disease now prevalent is mostly mild, the more deadly form might arise at any time. Indeed, such change in virulence has been noted in some epidemics. Curiously, smallpox is much more frequent in some of the less populous states, notably the eight Northwestern states. The better situation existing in the more heavily populated Eastern and Seaboard states was not always as good as it is now. The communities in which smallpox is now so relatively common may suffer a serious epidemic before the unnecessary ravages of the disease are stopped. The number of cases reported and the continued trend upward are a direct reflection of the percentage of unvaccinated among the population

THE TREATMENT OF MALARIA

The Fourth General Report of the Malaria Commission of the League of Nations² is especially valuable for its conclusions on the use of the newer synthetic drugs both in treatment and in prophylaxis. The report contains an adequate review of procedures and methods in different countries and it should be read by every one interested in the active treatment or the public health aspects of the disease. Experience has so far shown, the report states, that the eradication of malaria from a community by prophylactic treatment with drugs now available is virtually impossible. It is impossible in this way to reach in sufficient time all the inhabitants of a large area or even of a small village. Moreover, curative or prophylactic treatment may greatly diminish the morbidity, yet it cannot suppress the parasites in all the carriers. With regard to the choice of drugs for curative or prophylactic mass treatment, the report concludes that quinine still ranks first by reason of its clinical effectiveness and almost entire absence of toxicity. In certain circumstances, however, which are outlined in the report, atabrine and plasmochin offer a notable advance in the treatment and prophylaxis of malaria.

THE PRESIDENT-ELECT— DR. ROCK SLEYSER

The selection of Dr. Rock Sleyser, Wauwatosa, Wis., to be President-Elect of the American Medical Association, at the annual session in San Francisco, June 16, is a recognition of long and devoted service to organized medicine in the United States. For thirty-five years Rock Sleyser has continuously held a position of service to the medical profession. In 1903 he became secretary of the Calumet County Medical Society, continuing for six years. He was elected assistant secretary of the State Medical Society of Wisconsin and secretary in 1914. He remained as secretary until 1923 and was elected president in 1924. Since 1925 he has been treasurer of the society. From 1918 to 1923 Dr. Sleyser was editor of the *Wisconsin Medical Journal*. From 1915 to 1926 he served as delegate to the American Medical Association and during the last four years of that period was Vice Speaker of the House of Delegates. He became a trustee of the American Medical Association in 1926 and served continuously until June 1937, acting as chairman of the Board from 1935 to 1937. His professional record is likewise inspiring. He was graduated by the University of Illinois College of Medicine in 1902. After practicing medicine at Kiel and Appleton, Wis., he became physician to the prison for the criminal insane at Waupun, Wis.

Here he did research, much of which was reported in leading medical periodicals. Later he directed the building of the Wisconsin Hospital for the Criminal Insane and thereafter became medical director of the Milwaukee Sanitarium at Wauwatosa, which position he still holds. He is a fellow and has been a member of the board of governors of the American College of Physicians and a member of the American Psychiatric Association, the Association for Research in Nervous and Mental Diseases, and the Central Neuropsychiatric Association. It is a noteworthy fact in his career that Dr. Sleyser has been unanimously elected to every office which he has occupied, never having been opposed by any other candidate.

RUDOLPH MATAS RECEIVES DISTINGUISHED SERVICE MEDAL

The first medal for distinguished service to scientific medicine to be awarded by the American Medical Association was given to Rudolph Matas, surgeon, of New Orleans, by the House of Delegates in the election held June 13. The recipient of this medal is chosen by a process of selection which insures choice of an outstanding physician and scientist. This year the three names submitted to the House of Delegates after selective elimination of nineteen others were those of Drs. Simon Flexner, Ludvig Hektoen and Rudolph

Matas. Dr. Matas was born in Bonnet Carre, La., Sept. 12, 1860, was educated in Barcelona, Paris, Brownsville (Texas) and New Orleans, and was graduated by the Literary Institute of St. John, Matamoros, Mexico, in 1876. He received his degree in medicine from Tulane University in 1880 and has had honorary degrees from Washington University, the University of Alabama, Tulane University, the University of Pennsylvania, Princeton and the National University of Guatemala. He began the practice of medicine in New Orleans in 1880 and has specialized in surgery since 1895, when he became professor of surgery in Tulane University. He has been emeritus professor of surgery at Tulane and consultant at Charity Hospital, New Orleans, since 1928

ROCK SLEYSER, M.D.
PRESIDENT-ELECT OF THE AMERICAN MEDICAL ASSOCIATION

and honorary chief surgeon of Touro Infirmary since 1935. During the World War he was organizer and director of Base Hospital No. 24. He is a member of innumerable surgical societies throughout the world and at present is president of the Société internationale de chirurgie and honorary president of the International Surgical Congress, which will meet in Vienna next year. He has been decorated by the governments of Venezuela, Spain, France and Cuba. Dr. Matas is recognized as one of the most learned writers on surgery in the world. He is author of many treatises and monographs on surgical subjects, especially in the field of vascular surgery. By this award the American Medical Association indicates its recognition of scientific advancement as one of the main functions of organized medicine.

ORGANIZATION SECTION

PROCEEDINGS OF THE SAN FRANCISCO SESSION

MINUTES OF THE EIGHTY-NINTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT SAN FRANCISCO, JUNE 13-17, 1938

HOUSE OF DELEGATES

First Meeting—Monday Morning, June 13

The House of Delegates convened in the Empire Room of the Hotel Sir Francis Drake and was called to order at 10 a. m. by the Speaker, Dr. N. B. Van Etten.

Preliminary Report of the Reference Committee on Credentials

A preliminary report of the Reference Committee on Credentials was submitted by the chairman, Dr. Deering G. Smith, New Hampshire, who reported that 131 delegates with proper credentials had registered but that the number would be greatly increased before the first session of the House adjourned.

Dr. Smith announced that neither the delegate nor the alternate delegate from Rhode Island was in attendance but that Dr. Roland Hammond, who is the duly elected delegate from the Section on Orthopedic Surgery, had been appointed an alternate delegate from the Rhode Island Medical Society and wished to represent the Rhode Island Medical Society, which would permit the alternate delegate of the Section on Orthopedic Surgery to represent that section. On motion of Dr. Smith, seconded by Dr. A. T. McCormack, Kentucky, and carried, Dr. Roland Hammond was seated as a delegate from the Rhode Island Medical Society.

Adoption of Minutes of Atlantic City Session

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, that the House dispense with the reading of the minutes of the Atlantic City session.

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the minutes of the Atlantic City Session were adopted as printed.

Roll Call

Dr. Frederic E. Sondern, New York, moved that the roll call of the House be dispensed with since a number of the delegates had not yet completed their registration. The motion was seconded by Dr. George W. Kosmak, New York, and carried.

Distinguished Service Award

Dr. Arthur W. Booth, Chairman, Board of Trustees, reported that the Committee on Distinguished Service Awards had considered twenty-two names for the Distinguished Service Award of the American Medical Association and had submitted five names to the Board of Trustees. The Board of Trustees, in accordance with Chapter VI, Section 5, of the By-Laws, selected by ballot the following names for presentation to the House in alphabetical order: Simon Flexner of New York, Ludvig Hektoen of Chicago and Rudolph Matas of New Orleans.

The Speaker appointed as tellers for this meeting and for all meetings of the House at this session Drs. Francis F. Borzell, Pennsylvania, Chairman; Gunnar Gundersen, Wisconsin; Felix P. Miller, Texas; John Q. Myers, North Carolina, and Carl F. Vohs, Missouri.

The tellers spread the ballot and the Secretary announced that 136 votes were cast, of which Dr. Rudolph Matas received 75, Dr. Ludvig Hektoen 35 and Dr. Simon Flexner 26.

The speaker declared Dr. Rudolph Matas, who received a majority of the votes cast, to be elected by the House to receive the Distinguished Service Award of the American Medical Association.

Official Delegates from Foreign Countries

The Secretary informed the members of the House that Dr. C. H. Vrooman was attending the annual session of the American Medical Association as official delegate of the Canadian Medical Association and that Dr. Charles M. Greenslade would represent the New Zealand branch of the British Medical Association, both of whom would appear before the House later.

Messages of Sympathy

On motion of Dr. J. E. Paullin, Section on Practice of Medicine, seconded by Dr. H. B. Everett, Tennessee, and carried, a message expressing the sympathy and good wishes of the members of the House of Delegates was sent to Dr. Howard Morrow, San Francisco, Chairman of the Local Committee on Arrangements, who was seriously ill.

Dr. A. T. McCormack, Kentucky, moved that the House by a rising vote request the Secretary to send to Dr. E. H. Cary, Texas, who could not attend the session because of illness, its love and congratulations on his progress toward recovery and its regret because of his absence. The motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried unanimously.

Address of the Speaker, Dr. N. B. Van Etten

The Vice Speaker, Dr. H. H. Shoulders, Tennessee, presided while the Speaker, Dr. N. B. Van Etten, read his address, which was referred to the Reference Committee on Reports of Officers:

Members of the House of Delegates:

Centuries ago, in the days of Aesop, an elephant crashing through the woods broke down a small tree in which a bird was sitting on a nest, hovering her young. The mother bird was fatally injured. The elephant was very sorry and apologized in his best manner. The bird with her last expiration begged him to take care of her babies. This the elephant promised faithfully to do and, recalling what he had seen birds do in such an emergency, he carefully turned round and round and sat down on the nest.

Of course the elephant made a mess of it, which is what most of us do when we attempt something for which we have no aptitude or education. It may be presumed that the elephant knew the elephant business very well, but when he tried the bird business he was a little heavy in his technic.

As members of a great organization do we know our business? Are we properly mixing our sociology with our medicine? Are we really altruistic or are we dominated by a mass of individual economic desires? Are we "money mad doctors," as we are advertised on the cover of a June magazine? Are we thinking individually or collectively? Are we so interested in the science of medicine that we are losing a human interest in its application? Do we want more or better medical schools? Do we want more or better educated physicians? Do we want medical education controlled by organized medicine or by government bureaus? Do we, or do we not, correctly interpret the opinions of the medical profession of the United States? Are we so conservative that we are insensitive to social currents?

These questions are inspired by current criticism.

"Organized medicine is doomed," says one, unless it is "democratized." Notice has been given that we are to be investigated, excoriated, flagellated and perhaps excommunicated. It seems obvious that all this shooting is inspired. Why and by whom? Have we definitely departed from democracy? The American Medical Association was created for the

protection of the public from the misrepresentations of charlatans and quacks, for the promotion of the science and art of medicine and for the betterment of the public health. Are we carrying on in the spirit of the founders?

The American Medical Association is the largest medical organization in the world. Its technical setup is democratic by any test. Any member, anywhere, at any time may express himself on any subject with the greatest freedom before his county medical society, and if he meets approval there his opinions may travel to the larger audience of his state medical society and then to this House of Delegates for decisive action.

Evolutionary changes are inevitable, but representing, as you do, all of our states and territories, these changes are not likely to be revolutionary responses to the excitement of occasional individuals among our more than 109,000 members, or servile responses to inspired propaganda. When county societies become interested in new medical service plans and transmit their ideas to state societies, which in turn send them to your sessions, you will discuss them as you have always done, and when a majority of you approve them they will be adopted and carried out by your executives.

By constitutional provision "The legislative powers of the Association reside in the House of Delegates. The House of Delegates shall transact all business of the Association, not otherwise specifically provided for in this Constitution and By-Laws, and shall elect the general officers."

You elect the officers and trustees and they report to you. They do not originate policy. You make the policies, and the officers and trustees are obligated to execute them. If your policies are not carried out to your satisfaction, you may replace your officers. On your shoulders rests the fate of American medicine. Every practitioner of medicine looks to you, and back of these practitioners are millions of people who are daily looking for the best in medical care, not merely adequate care of just any medical care that may be promised by paternalistic bureaus, but a constantly improving medical care that a constantly improving medical profession may offer them.

There can be no autocracy where final decisions rest within a house composed of 175 delegates. There is no dictator among your officers. There is no dictator among the trustees to whom you delegate the care of your money. There is no policy which you may not reverse. You have the power and you have the responsibility. As delegates from constituent bodies it is your duty to report the action of this house to your membership. Judging from the lack of knowledge of the Association among physicians, and judging from the amount of misrepresentation about the American Medical Association which constantly appears in public print, it seems evident that you do not sufficiently exercise intelligent interpretation of the Association to your members at home.

If this great Association is a blundering elephant, remember that you are riding him.

If this great Association is unresponsive to the will of its membership, remember that you may have failed to bring the thought of your constituents to this forum. This is a great association. The Scientific Assembly became so large that you divided it into sixteen sections, where every specialty may be discussed in the best possible manner and where there is ample opportunity for the voice of modern medicine. Other medical societies employ different techniques. It is within your province to develop other models if you wish. Your Judicial Council, your Council on Medical Education and Hospitals and your Council on Scientific Assembly are standing committees of the Association and they report to you.

A delegate raises the objection that the sessions of the House are too short to digest properly questions which arise from resolutions that are presented, and that hasty judgments are likely to result. Your councils meet throughout the year. You may appoint special committees to carry on continuous studies as you have done in the past, and finally you may call special sessions to meet a serious need.

You are amply implemented by your Constitution and By-Laws. If you are unhappy about the conduct of the Association you have only yourselves to blame. Your Speaker makes no recommendations. He has restated your powers to renew your consciousness of them and to stimulate their faithful exercise.

Your Speaker is gratefully appreciative of the unvarying courtesy of this legislature and as the time has come for him

to retire from official places he does so with sincere regret that he will miss his contacts with you. He has faith in the success of the medical profession in riding out disgruntled criticism, and he believes that the general sanity of the American people will lead them to support an honest medical service such as is offered by the American Medical Association.

NEW MEMBERS

Twenty-two delegates are here for the first time. In order that they may be properly identified, I will ask them to rise and remain standing while all their names are called:

Arkansas, Edward E. Barlow; California, J. P. Nuttall; Delaware, William H. Speer; Illinois, R. K. Packard; Indiana, George R. Dillinger; Iowa, A. D. Woods; Massachusetts, Edward L. Merritt, David D. Scannell, Dwight O'Hara, Walter G. Phippen; Michigan, L. G. Christian; Missouri, H. L. Kerr; Nebraska, Karl S. J. Hohlen; New Jersey, Andrew F. McBride, S. T. Snedecor; New York, Robert F. Barber, James M. Flynn, James R. Reuling Jr., Louis H. Bauer, George F. Newton; Ohio, John B. Alcorn; Vermont, B. F. Cook; West Virginia, Ivan Fawcett; Philippine Islands, Henry W. Daine; United States Army, Roger Brooke; Section on Preventive and Industrial Medicine and Public Health, R. R. Sayers.

I desire to give you a hearty welcome and an assurance that you will be recognized when you rise and that your communications will have a hearing. In common with all the members of this house, you are instructed to follow your resolutions to the sessions of the reference committees. All reference committees will meet immediately after the close of this session for organization, and all delegates are assured that the committee rooms will be open for free discussion of all referred matters.

Since the last session at Atlantic City, in June 1937, many former officers or members of the House of Delegates have gone beyond our vision. The reading of their names will awaken personal memories. The dates following their names indicate their years of service.

A. H. Barkley, Kentucky, 1914.
Walter J. Barlow, California, First Vice President, 1911.
L. G. Bowers, Ohio, 1926.
Walter V. Brem, California, 1923.
E. D. Clark, Indiana, 1907.
Blase Cole, New Jersey, 1937.
Elmer B. Coolley, Illinois, 1918.
Rufus J. Coultas, Illinois, 1912-1913, 1918-1920.
William E. Darnall, New Jersey, Fourth Vice President, 1914.
John P. De Witt, Ohio, 1923-1937.
L. C. Feemster, Mississippi, 1915.
Willard D. Haines, Ohio, 1921-1924.
J. N. Jenne, Vermont, 1908, 1910, 1929.
Daniel Fiske Jones, Massachusetts, 1921.
William H. Kennedy, Indiana, 1926.
Samuel E. Lambert, Washington, 1920-1921.
Edgar J. March, Ohio, 1911-1912.
A. C. Messenger, Ohio, 1924.
W. W. Lazarus, Pennsylvania, 1932.
Henri P. Linsz, West Virginia, 1918, 1920-1930.
Theodore P. Livingston, Nebraska, 1909.
F. A. Long, Nebraska, 1907-1908, 1911.
J. Curtis Lyter, Missouri, 1922, 1924-1925.
Walter J. Miller, Tennessee, 1903, 1905-1906.
William L. Noble, Illinois, 1912, 1914-1915.
Guy S. Peterkin, Washington, 1909, 1915.
William M. Robertson, Pennsylvania, 1916.
Dunbar Roy, Georgia, 1910-1911, 1914.
Samuel Wolfe, Pennsylvania, 1907-1910.
George H. Scott, U. S. Army, 1933.
George L. Strader, Wyoming, 1908.
Harry V. Wurdemann, Washington, 1902, 1906, 1914.
George H. Simmons, Chicago, Secretary, 1900-1911; Editor, 1903-1911; Editor and General Manager, 1911-1924; Editor and General Manager Emeritus, 1924-1937.

Dr. Simmons attended the sessions of the House last June and was present at the delegates dinner. He exhibited much of his old enthusiasm for the Association, for the success of which he was largely responsible. His sanity and loyalty are needed today. He will be long remembered.

As life runs on, the road grows strange
With faces new; and near the end
The milestones into headstones change
'Neath every one a friend.

—James Russell Lowell

At the request of the Vice Speaker, the members of the House rose and stood for one minute in silent tribute to the memory of departed delegates.

Reference Committees

The Speaker presented the following names of members of Reference Committees:

SECTIONS AND SECTION WORK

Robert A. Peers, Chairman.....California
Arthur J. Bedell.....Section on Ophthalmology
Burt R. Shurly.....Section on Laryngology, Otology and Rhinology
Edward H. Skinner.....Section on Radiology
Tom B. Throckmorton.....Section on Nervous and Mental Diseases

RULES AND ORDER OF BUSINESS

W. H. Seemann, Chairman.....Louisiana
Lewis B. Bates.....Isthmian Canal Zone
Edgar A. Hines.....South Carolina
J. Newton Hunsberger.....Pennsylvania
Roland Hammond.....Rhode Island

MEDICAL EDUCATION

William D. Johnson, Chairman.....New York
John W. Amesse.....Colorado
J. C. Flippin.....Virginia
McLain Rogers.....Oklahoma
Walter E. Vest.....West Virginia

LEGISLATION AND PUBLIC RELATIONS

Terry M. Townsend, Chairman.....New York
W. Albert Cook.....Oklahoma
Charles A. Dukes.....California
Henry Cook Macatee.....District of Columbia
Walter B. Martin.....Virginia

HYGIENE AND PUBLIC HEALTH

H. B. Everett, Chairman.....Tennessee
Charles H. Goodrich.....New York
J. F. Hassig.....Kansas
Charles S. Skaggs.....Illinois
Joseph F. Smith.....Wisconsin

AMENDMENTS TO CONSTITUTION AND BY-LAWS

H. A. Luce, Chairman.....Michigan
Herbert L. Bryans.....Florida
George P. Johnston.....Wyoming
Charles J. Whalen.....Illinois
Raymond L. Zech.....Washington

REPORTS OF OFFICERS

J. N. Baker, Chairman.....Alabama
Elbridge J. Best.....California
Ben R. McClellan.....Ohio
Richard H. Miller.....Massachusetts
Arthur C. Morgan.....Pennsylvania

REPORTS OF BOARD OF TRUSTEES AND SECRETARY

Frederic E. Sondern, Chairman.....New York
Clyde L. Cummer.....Section on Dermatology and Syphilology
John H. Fitzgibbon.....Oregon
Fred W. Rankin.....Section on Surgery, General and Abdominal
Felix J. Underwood.....Mississippi

CREDENTIALS

Deering G. Smith, Chairman.....New Hampshire
R. W. Fouts.....Nebraska
James R. McVay.....Missouri
William H. Myers.....Georgia
William R. Molony Sr.....California

MISCELLANEOUS BUSINESS

Fred Moore, Chairman.....Towa
E. S. Hamilton.....Illinois
Walt P. Conaway.....New Jersey
F. S. Crockett.....Indiana
E. L. Henderson.....Kentucky

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, the House consented to the appointment of a Reference Committee on Executive Session.

EXECUTIVE SESSION

J. D. Brook, Chairman.....Michigan
W. F. Braasch.....Minnesota
William R. Brooksher.....Arkansas
Don F. Cameron.....Indiana
Meredith Mallory.....Florida

SERGEANTS AT ARMS

Holman Taylor.....Texas
Howard C. Frontz.....Pennsylvania

Address of President J. H. J. Upham

The Speaker resumed the Chair and presented the President, Dr. J. H. J. Upham, Columbus, Ohio, who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

The opportunity of visiting many state and district medical society meetings in practically all sections of the country has given me three outstanding impressions concerning the state of medicine and medical organization in this country:

First is the evident desire, even avidity, of the general membership of the medical profession for self improvement in the newer developments of medical knowledge. This is evidenced by the great number of medical societies at present in existence providing programs to meet all varieties of medical practice. There are at the latest listing 100 national special societies holding yearly meetings. In addition there are numerous district meetings of similar character, to meet the demands of sectional areas. These are purely scientific assemblies, and the opinions and expressions of the members attending have a weight and authority that are duly acknowledged if confined within the bounds of medical science.

When, however, such societies take action on matters of medical policy, or officers of these organizations seize the opportunity to attract public notice by expressing personal opinions outside the real scope of the society, they collectively or individually arrogate to themselves an authority and importance that cannot be conceded by the rest of the medical profession—echoes from the public press to the contrary notwithstanding!

Added to these special societies are the regular state and county meetings, the hospital staff gatherings, the growing practice of postgraduate assemblies for the alumni of many colleges, and the postgraduate courses carried on by several state associations. One cannot but wonder whether this activity is not being somewhat overdone, and yet from a questionnaire sent to cross section areas the attendance of members reported was remarkably good and a review of a large number of programs shows a catering to a high plane of medical thought. One must feel therefore that the supply is in response to a definite and a general demand.

A second impression is of the awakened interest of our membership in the present social and economic questions confronting the country as a whole and especially those connected with present day medical practice. Ten years ago the average practitioner accepted the care of the indigent as a professional duty and an accepted duty. The great depression, however, made this burden too great to be carried further by our profession alone and forced collective thinking of ways and means of meeting the situation. In every state and in almost every county the various phases of this problem are being discussed. The best thought of our members is being given to meeting the difficulties in their respective areas. Furthermore, it is my distinct feeling that the activities manifested are not the result of fear of the imposition of any European scheme of socialized practice but rather an aroused consciousness of the part organized medicine should play in seeking to solve the present economic problems in relation to illness. Allied to this is the manifest determination to preserve the individual type of medical practice as that best suited to this country, and to maintain that practice on the highest possible plane.

In the current effort to secure definite and countrywide information as to needs of medical care and the supply at present existing in every community, the American Medical Association has assumed a leadership in constructive thought that is a noteworthy contribution. When the basic facts are established a long step will have been taken in the direction of solving some of these many grave problems. One concrete evidence of this arousing of the members of our profession, and in their feeling that our greatest hopes lie in a united profession, is the remarkable increase in membership of this Association. The latest report shows 109,435 actual members. This is our emphatic response to the press reports of dissension in our organization.

The third impression is that of the awakening of our membership to the obligations of medicine and medical practice. The scientific investigations of fifty years ago laid the foundation of preventive medicine. The record of progress made in these fifty years is one of wonderful achievement. It has led to the grouping of physicians into those occupied chiefly in scientific research, those engaged in public health work or preventive medicine, and the remainder in curative practice.

The developments of recent years have shown that social and economic conditions are inseparably intermingled with health and sickness. There are factors beyond the ability of physicians alone to supply that enter into many present day problems. This was first shown on a large scale in the nine-

ties as a result of the worldwide interest in tuberculosis following the discovery by Koch of tuberculin. Before that time tuberculosis was practically relegated to the medical profession, but with the focusing of attention on this, the then greatest single destroyer, there developed the need of improved sanitation, protection of the workers in industry, the providing of opportunity for prolonged periods of complete rest, proper nourishment and particularly the education of the public, especially of those in contact with the disease. The enlistment of intelligent and interested members of the public in cooperation with members of our profession has led to gratifying results in forty years and this must be continued for many years to come.

Following this lead we have seen similar campaigns against cancer, heart disease, maternal and child welfare, and lastly the recently inaugurated campaign against syphilis. These movements are the result of an aroused public interest. They are an inevitable product of modern civilization, and the medical profession cannot stand aloof. It is of great importance that organized medicine take cognizance of these movements, not necessarily officially, but through physician members with the medical point of view to guide these organizations along the lines of procedure most advantageous to the actual and prospective individuals affected and for the public as a whole.

This fight against syphilis parallels that of tuberculosis in many ways, especially in the need of popular education and the stressing of the value of prolonged treatment. Particularly in these fields is wisely directed public effort of value. In the campaign against syphilis there are certain advantages over that against tuberculosis, in that syphilis is not so disabling in the early stages, does not require sanatorium treatment and is not connected with industrial hazards or insanitary living conditions. It is, however, so dependent on fundamental human frailty that it is almost equally difficult to control.

While we possess a specific cure for syphilis if adequate treatment is given, it is beyond the power of the medical profession to meet the demand alone. The present agitation is a definite challenge to our profession which must be met squarely. Through cooperation with lay efforts, popular education may be wisely directed and efficiently carried on. The tabu of silence has already been broken, and early and prolonged treatment is being stressed by both lay and medical workers. This is of great importance but after all is but preliminary or auxiliary to the real task of treatment, which is definitely our field and our responsibility. One might think superficially that this is the major concern of the syphilologists and genito-urinary specialists, but the number of individuals affected is so great and their distribution so wide, many living in rural areas not accessible to specialists, that the general practitioner must play an important part in the program.

The necessary expense of prolonged treatment is also a factor which makes this necessary. As is usually the case, the extremes of society, the high and the low, are not affected. The upper classes can take care of the costs of specialists, and the indigent are being cared for, partially at least, by dispensaries or clinics, with many of the state or local boards of health supplying the necessary drugs. In areas not at present supplied, this could be supplemented by plans worked out by representatives of the county medical society, the local board of health and the community fund or other social agency to form a joint governing body to open treatment centers, the medical group to furnish the medical personnel and be responsible for the treatment, the health board to furnish the drugs and supplies and the social agency to investigate the social status of the clientele and carry on follow-up work.

The middle class in general may be cared for effectively by the general practitioner, but the lower middle class and those on the borderline of medical indigence constitute a serious phase of the problem. Many refuse to go to a free clinic but are deterred from seeking adequate treatment because of the expense. Some of these patronize quick-cure charlatans or buy worthless quack remedies. In view of the greatly simplified modern technic our medical societies in many places are meeting this issue by mutual agreement of the members to charge these individuals fees commensurate with their circumstances, particularly remembering the long period required for adequate treatment. A plan might be drawn by the com-

posite governing body I have mentioned that would include the furnishing of drugs and supplies for those reluctant to go to a free clinic but able to pay a small fee for the actual service of the physician. In this way the self respect of these patients may be preserved and many saved the devastating effects of ineffectual or practically worthless treatment.

In view of the wide publicity given the antisiphilic movement and the necessary part in it that the medical profession must play, the attention of the state and county societies should be drawn to the opportunity of assuming a definite leadership in the respective states and counties, and of directing the movement with the best ideals of medicine and for the best interests of the public.

Address of President-Elect Irvin Abell

The Speaker presented the President-Elect, Dr. Irvin Abell, Louisville, Ky., who delivered the following address, which was referred to the Reference Committee on Reports of Officers:

Mr. Speaker and Members of the House of Delegates:

As your President-Elect it has been my duty and my privilege to attend the deliberations of your Board of Trustees and many of the district and state association meetings throughout the country. The most lasting impression I have gained from these widespread contacts is the sincere desire of the members of the American Medical Association to preserve our system of medical care and at the same time to make its benefits available to all classes of our population. Differences of opinion there have been and will continue to be as to the best method of accomplishing the latter aim, but I have found nowhere basis for the unwarranted accusation that organized medicine as a whole is static and obstructive. True it has opposed, does now oppose and will continue to oppose proposals that tend to lower the standard which it has set on medical service; namely, that it be good medical service. By no possible deduction can this be interpreted as a selfish action, one that would inure to our own aggrandizement. By tradition and heritage we are committed to the principle that the sole reason for the existence of our profession is the service it can render humanity. The highest service it can render the people of this country consists not only in healing the sick and preventing disease but in preserving that system of practice, evolved through years of studious and unselfish effort, which has given to the people of the United States the lowest morbidity and mortality rates of any country in the world.

The members of the Association have welcomed with enthusiasm the resolutions adopted by the Board of Trustees following a meeting in which representatives of the American Public Health Association and the United States Public Health Service participated. They see in this an opportunity to continue the constructive service of organized medicine to the people in solving the problem of a wider distribution of medical service without sacrificing or compromising the principles and precepts which are recognized as essential to good medical care. While our critics have rather vociferously demanded a plan, our membership, with a better understanding, an accumulated knowledge and a broader experience bearing on the problem than any other interested body, has wisely refrained from making a "snap diagnosis" with its inevitable inaccurate "therapeusis" until the needs for medical care and preventive medicine can be precisely known.

In any consideration of the indigent and the low income groups, social and economic factors play parts of equal importance with medical care. It is essential that the reciprocal relations of each be given careful consideration, to the end that medical and professional standards do not suffer as a result of projected experiments in legislative planning for socialization in various fields. The medical profession, from prolonged and intimate observation, is fully cognizant of the social and economic needs that lie so heavily on the indigent and the low income groups. While willing to do its share in their rehabilitation, the medical profession does not feel it within its power or province to initiate or sponsor measures looking toward social and economic reformation. At the same time it resists efforts and proposals that would include and regiment its services under lay control to the accomplishment of these ends.

There is no definite means of computing in monetary valuation the services voluntarily rendered to the indigent and low income groups by the medical profession during the past eight years. From such data as are available a fair estimate based on a minimum fee schedule would place the valuation in the neighborhood of a million dollars a day, a contribution not equaled or exceeded by any agency other than the federal government.

Surely this offering for the public good would indicate that medicine has more than fulfilled the obligation implied in its Principles of Medical Ethics to give of its services to the needy and that as a profession our ideal and our aim have been the provision of service rather than solicitation for compensation. The fact that the requirement and demands of the indigent and low income groups have reached such proportions as to constitute a load beyond the capacity of the profession to absorb and carry has brought to the fore the proposal that these needs be met by the application of federal funds. If such a change is to come, it is essential both for the future progress of medicine and for the welfare of the groups to be served that the distribution and direction of such funds be made neither under political control nor under lay domination. The health of the nation should neither be made the football of politics nor consigned to the fallacious judgment of those who, regardless of their sincerity of purpose, are untrained in the intricacies of its care. With accurate knowledge concerning the variations in the availability of medical service and in the facilities for its dispensation and as well in the demands for such in every county in the country, it will be possible for the Association to evolve methods that will make possible the provision of care to those unable to provide it themselves.

The economic level in the states and counties ranges all the way from opulence to poverty; many are abundantly able financially to meet their obligations to society, including the care of their indigent; some are apparently so poor that they are unable to meet the expense of their local governmental activities. The problem of medical care in the former group does not present the complexities found in the latter, and, while the provision of medical care to it will meet a humanitarian impulse, it will not alone solve its problems.

It is difficult for us to understand the attitude of the socially minded statesmen who would supply this group with medical care at governmental expense with a lowering of the efficiency, and perchance integrity, of a part of the medical profession and without providing for the beneficiaries a standard of living that would maintain their own respect as free American citizens. The American people are not willing to accept a collectivist or communal society. There are assuredly no good grounds to assume their volition to subject the medical profession to such an experiment. When the suggestions of this House of Delegates based on the study undertaken by the Association will have been presented to the public, the thoughtful will have concrete evidence that we have not been recreant to the faith reposed in us but that with a fortitude developed from the accomplishments of the past we stand ready to salute a more splendid future.

A second matter of widespread interest concerns graduate education, a problem that fortunately is well under way to solution under the direction of the Council on Medical Education and Hospitals, its objective being to improve the qualifications of physicians and thereby to enhance the quality of medical service. The growth and development of knowledge in the art and science of medicine during the present century have been unprecedented: its accumulation has been so rapid and so extensive as to upset all previous conceptions as to both the acquisition and its distribution. Not only is the recent graduate perplexed in preparing himself for a career in medicine, but the graduate of some years who has not kept abreast of the current finds himself woefully lacking in the newer knowledge and procedures, with a consequent failure in understanding of their principles, application and usefulness. The American Medical Association, in consonance with its aim of maintaining a high standard in medical practice, has always insisted that the quality of medical care be good. To be good it must embrace and utilize the constantly accumulating fund of knowledge accruing from study, from research, from clinical

investigation and from scientific evaluation of all that is proposed for its advancement. The newer knowledge, thoughts and concepts meeting these requirements are so great that graduate medical education has forged to the front as one of the important problems confronting the profession today. It presents two phases, one dealing with the preparation and training of specialists, the other dealing with the continued education of those who are not specialists. Because of the enormous elaboration of the details of medicine, as of other sciences, there has been a corresponding growth of specialism in medicine and in research. Twelve examining boards have been created for the certification of specialists in their respective fields, which demand of the candidate requisite training and a demonstration of efficiency before the stamp of approval as specialist, attesting the attainment of skill and knowledge, may be obtained. Medical schools and hospitals are utilized in the graduate training of specialists, while the schools, the hospitals and the state medical associations cooperate in providing opportunities for the further training of those who are not specialists. The entire problem of graduate education is at present being made the subject of intensive study by the Council on Medical Education and Hospitals with the objectives of developing opportunities for its acquirement, establishing criteria for the schools and hospitals engaging in it, and formulating programs and courses of study for those desiring to take advantage of it.

The scientific trends of American medicine, as evaluated by the contributions of the past year made in the component units of the American Medical Association and in its literature, can be viewed with optimism. Remarkable advances and progress are being charted in every field, but the words of Dr. George Shattuck, uttered as far back as 1866, still hold true: "No one can deny or doubt that we have made and are making great advances, but the horizon opens before us as we go on, and the extent of the field becomes even more apparent than our progress."

REPORTS OF OFFICERS

Report of the Secretary

Dr. Olin West presented his report as Secretary, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, with the exception of that portion dealing with proposed amendments to the Constitution, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Report of Board of Trustees

Dr. Arthur W. Booth, Chairman, presented the report of the Board of Trustees, which was referred to the Reference Committee on Reports of Board of Trustees and Secretary, except those portions referring to the Bureau of Legal Medicine and Legislation and to the Bureau of Medical Economics, which were referred to the Reference Committee on Legislation and Public Relations, and that portion referring to contraceptive devices, which was referred to the Reference Committee on Executive Session.

In addition to the report of the Board of Trustees as printed in the Handbook, Dr. Arthur W. Booth, Chairman of the Board of Trustees, presented the following supplementary report:

REQUESTS FROM THE AMERICAN RED CROSS FOR APPROVAL OF ITS MEDICAL POLICIES IN DISASTER

The following statement of the medical policies of the American Red Cross in disaster was submitted to the Board of Trustees by the medical adviser, William De Kleine, with a request for approval by the Association and is referred to the House of Delegates for its consideration:

SECTION VII. MEDICAL AND NURSING SERVICE: I. POLICIES

The primary responsibility for the care of the sick and injured in disasters rests with the local physicians. Red Cross medical service does not substitute for the services of local physicians and dentists but cooperates with them and assists by organizing and directing the medical relief work and by providing the facilities which they lack and need for the emergency.

Every effort is made to maintain, and reestablish as quickly as possible, the predisaster relationships between physicians and dentists and their patients. In the first few days it is often necessary to apply aid on a mass basis in emergency medical stations. This practice is discontinued as soon as possible and patients referred to their own physicians and dentists.

Red Cross medical and dental assistance is intended only for those who are ill or injured because of the disaster and who because of lack of resources are unable to obtain care. Exceptions may be made in certain emergencies (obstetrics, for example) when medical service is not otherwise available.

If possible, the Red Cross medical officer after completing his first survey, otherwise the director, should confer with local physicians, dentists and hospital officials, preferably through the local medical and dental societies, to explain Red Cross medical policies and procedures.

It is hoped that physicians and dentists, like other community leaders engaged in various phases of disaster relief work, will give their services on a volunteer basis for patients unable to pay. On approval of the director, actual expenses incurred and cost of supplies used by physicians and dentists may be paid those volunteering their services. Physicians should not be paid for work during the emergency period unless they have been previously employed for that purpose. The Red Cross recognizes that this schedule of fees is merely an attempt to share the burden resting on the medical and dental professions and does not fully compensate on the basis of all professional schedules. Where volunteer service is not available or compensation is desirable, the fees allowed should not exceed the amounts indicated in the following paragraphs without prior approval of the vice chairman.

If physicians or dentists are needed for either part or full time duty at emergency medical stations, emergency hospitals, concentration centers, for assisting health officials in immunization work or making home visits on a mass basis, they may be employed at not to exceed \$10 per day for full time and proportionately smaller amounts for part time duty. If employed on an hourly basis (one to three hours only) the rate should not exceed \$2.50 per hour. An additional amount of 5 cents per mile may be allowed if they use their automobiles for transportation.

Arrangements for medical and dental services on an individual patient basis may be authorized following the usual Red Cross disaster case work processes.

If physicians not employed on a part or full time basis are needed for making home visits, attending obstetric cases or other service, particularly in rural territory, arrangements may be made on an individual patient basis. Arrangements may be made for a limited number of calls per patient at the prevailing local fee, but not to exceed \$3 per visit, plus 25 cents per mile (one way) for calls in rural areas and not to exceed \$20 for attending an obstetric case, including one or two postpartum visits, plus 25 cents per mile (one way) for each call in rural areas. No mileage allowance shall be made for visits within the corporate limits of a city or village where the physician resides.

Glasses may be fitted, dental plates made and laboratory service and x-ray examinations obtained at the prevailing local rate. When a considerable number of x-ray examinations are required, a reasonable reduction is desirable.

One to two dollars per visit may be allowed for a limited number of office visits, and three to five dollars for a physical examination.

A surgical fee should not exceed \$50 except in very highly specialized fields such as orthopedic and plastic surgery, or in unusually severe injuries requiring a long period of treatment.

When the illness or injury of a disaster patient is complicated with a preexisting disease such as a venereal disease, allowance may be made for the purchase of medical supplies sufficient for a limited course of treatment to insure his prompt recovery or to make him noninfectious.

Occasionally when a disaster causes a large number of mutilating injuries and the care of disaster patients interferes extensively with the regular practice of physicians, compensation may be on the basis of a lump sum honorarium for all patients

regardless of their number or the duration of their illnesses. Any such arrangement must have the prior approval of the vice chairman.

With the approval of the director, the medical officer or his representative will plan and arrange for professional compensation.

Reasonable hospital rates may be paid for the care of patients including ordinary service, medicines, dressings, operating room, etc. (for disaster caused illnesses or injuries), on a case work basis. Ward rates are generally considered reasonable. Commitments should not be made until they have been approved by the director. Verbal agreements between hospitals and the Red Cross will be given written confirmation by the director.

Authorization to physicians to write prescriptions for disaster patients should be granted only on an individual case basis. Druggists should be informed of this policy and instructed to fill prescriptions as a charge against the Red Cross only when each prescription is accompanied by a disbursing order.

Report of the Judicial Council

Dr. George Edward Follansbee, Chairman, presented the report of the Judicial Council, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws.

Report of the Council on Medical Education and Hospitals

Dr. Ray Lyman Wilbur, Chairman of the Council, presented the report of the Council on Medical Education and Hospitals, together with supplementary reports, which was referred to the Reference Committee on Medical Education:

SUPPLEMENTARY REPORT: ESSENTIALS OF AN ACCEPTABLE MEDICAL SCHOOL

I. ORGANIZATION

A medical school should be incorporated as a nonprofit institution. Its board of trustees should be composed of public spirited men or women having no financial interest in the operations of the school or its associated hospitals. The trustees should serve for fairly long and overlapping terms. If the choice of trustees is vested in any other body than the board itself, that fact should be clearly stated. Officers and faculty of the school should be appointed by the board.

II. ADMINISTRATION

There should be careful and intelligent supervision of the entire school by the dean or other executive officer who, by training and experience, is fitted to interpret the prevailing standards in medical education and who is clothed with sufficient authority to carry them into effect.

There should be a good system of records showing conveniently and in detail the credentials, attendance, grades and accounts of the students, by means of which an exact knowledge can be obtained regarding each student's work. Records should also be kept showing readily the attendance of students at the teaching hospitals and dispensaries and the maternity and post mortem cases attended.

The school should require that students be in actual attendance within the first week of each annual session and thereafter. Except for good cause, such as for illness, no credit should be given for any course when the attendance has been less than 80 per cent of the full time.

The school should issue, at least annually, a bulletin setting forth the character of the work which it offers. Such announcement should contain a list of the members of the faculty with their respective qualifications. The courses available should be set forth by departments (anatomy, physiology and so on) showing for each course its number, subject, content, character (lecture, recitation, laboratory or clinic), length of time, when, where and by whom given, and the amount of credit allowed. Information should be given regarding entrance requirements and tuition fees. The names of the students enrolled during the current or previous sessions should also be included.

The number of students to whom an adequate medical education can be given by a college is related approximately to the laboratory and hospital facilities available and to the size and qualifications of the teaching staff. A close personal contact

between students and members of the teaching staff results in an efficiency which is not possible in an institution where the number of students is excessive.

Advanced standing may be granted to students for work done in other acceptable medical schools, and in granting advanced standing there should be no discrimination against the school's full course students. Official verification of the student's previous medical work should be obtained by direct correspondence with the school from which he comes, and his preliminary qualifications should also be verified and recorded the same as for freshmen students.

The admission of students to the medical school must be in the hands of a responsible committee or examiner, whose records shall always be open for inspection. Documentary evidence of the student's preliminary education should be obtained and kept on file. When the medical school is an integral part of the university, this work usually devolves on the university examiner. Unless the university examiner and his records are closely accessible, however, some officer at the medical school should obtain and keep on file each student's academic records.

III. FACULTY

The school should have a competent teaching staff, graded and organized by departments. Appointments should be based on thorough training, successful teaching experience, ability in research, and willingness to pursue an academic career. In the clinical departments this does not exclude men who are in the active practice of medicine and surgery. Nominations for faculty positions should originate in the faculty, usually being made by the dean in consultation with the department heads or a committee of the faculty. Reasonable security of tenure must be assured in order that the personnel of the faculty may have adequate stability. In the preclinical sciences the faculty should include at least ten qualified persons of professorial rank,¹ devoting their entire time to teaching and to that research without which they cannot well keep up with the rapid progress of medical science. For each twenty-five students in a class there should be at least one full time assistant in each of the preclinical departments. Salaries should be sufficient to enable members of the faculty to support themselves and their families without the necessity of devoting time and energy to other occupations.

IV. PLANT

The school should own, or enjoy the assured use of, modern fireproof buildings sufficient in size to provide lecture rooms, class laboratories, small laboratories for the members of the teaching staff and advanced students, administrative offices and a medical library. Equipment should be adequate, both for student use and for research. A trained librarian should be employed to supervise the operation and development of the library, which should include the more modern text and reference books with the *Quarterly Cumulative Index Medicus*, the *Index Catalogue of the Library of the Surgeon-General's Office* and serviceable card indexes. The library should receive regularly the leading medical periodicals, the current numbers of which should be readily accessible. These periodicals should be bound without delay.

There should be provision for the collection, preservation and indexing of anatomic, embryologic, pathologic and other specimens. With each pathologic specimen coming from post-mortems there should also be kept the record of the postmortem, the clinical history of the patient on whom the necropsy was held, and microscopic slides showing the minute structure of the disease shown in the gross specimen. The museum furnishes an excellent means of correlating the work of the department of pathology with that of the clinical departments.

There should be sufficient dissecting material to enable each student to dissect at least the lateral half of the human cadaver, to provide cross sections and other material for study and demonstration.

For experimental laboratory work, as well as for medical research, a supply of animals is essential. Proper provision is necessary also for the housing and care of such animals. In any use made of animals every precaution should be taken to prevent suffering, and work by students should be carefully supervised.

1. Professorial rank as here used includes professors, associate professors and assistant professors.

Each school should have such useful auxiliary apparatus as stereopticons, reflectoscopes, microprojectors, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, x-ray apparatus, and other aids to effective teaching.

V. CLINICAL FACILITIES

The school may own or control a general hospital. By control is meant the unquestioned right to appoint the attending staff. In this event the students come into close and extended contact with patients under adequate supervision. In the event that a medical school depends for clinical teaching on an independent hospital, it is essential that the clinical teachers, either on nomination by the school or by agreement in conference between school and hospital, be appointed by the hospital trustees to appropriate positions on the hospital staff. Such hospitals should be in close proximity to the school and have a daily average of not less than 200 patients who can be utilized for clinical teaching, these patients to be of such character as to permit the students to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties. In the use of this material, bedside and ward clinics should be developed for sections of from five to ten students; and patients in medicine, surgery and the specialties should be assigned to each student under a well supervised clinical clerk system. The treatment and care of these patients should be particularly observed and recorded by the student under the strict supervision of the intern, the resident or the attending staff of the hospital. The use of existing municipal or state hospitals for teaching purposes is also advised.

The school should also own or control ample hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

The school should own or control a well ordered dispensary or outpatient department with a daily average attendance of at least 100 patients (visits). Good histories and records of the patients should be kept and the material used in medical instruction. The attending staff should be drawn largely from the faculty, including those of highest rank.

At least fifteen maternity cases should be provided for each senior student, who should have actual charge of these cases under the supervision of the clinical instructor. A carefully prepared report of each case should be handed in by the student.

Facilities should be provided for at least fifty necropsies during each school session which are attended and participated in by students. These should be performed by the professor of pathology or a member of his staff. The material thus secured should be used in connection with clinical pathologic conferences.

VI. RESOURCES

Experience has shown that modern medicine cannot be acceptably taught by a school which depends solely on the income from students' fees. No medical school, therefore, should expect to secure approval which does not have a substantial income in addition to students' fees. This statement carries double weight if the school finds it necessary to maintain its own teaching hospital.

VII. REQUIREMENTS FOR ADMISSION

1. The minimum requirement for admission to approved medical schools is two years of college training which include English, theoretic and practical courses in physics, biology, and general and inorganic chemistry. Three years or more in college is, however, recommended.

2. Since it cannot in general be assumed that all who have satisfied these requirements merely in terms of hourly credits are fitted for the study of medicine, it is desirable that qualitative standards for admission should be imposed.

3. As a rule candidates should have received their preliminary education in institutions approved by accrediting agencies acceptable to the Council. Exception to this rule may be made in the case of applicants who have demonstrated superior ability. For the convenience of admitting officers the Council has prepared a list of colleges of arts and sciences approved by national and regional educational associations.

4. Admission to approved medical schools may also be by examination under the following conditions:

(a) Candidates who have completed two years of collegiate instruction and present evidence of general scholarship of high order, but who lack credits in not more than two of the required subjects, may be admitted on passing examinations in these subjects.

(b) Candidates who have completed three years of collegiate instruction and present evidence of having accomplished work of distinction in one or more fields of learning, but who lack credit in any or all of the required subjects, may be admitted on passing examinations in these subjects.

VIII. CURRICULUM

The entire course of four academic years should consist of from 3,600 to 4,400 hours, distributed as from 900 to 1,100 hours a year, and shall be grouped as set forth in the following schedule, each group to be allotted approximately the percentage of hours of the whole number of hours in the courses as stated:

	Number	Per Cent.
1. Anatomy, including embryology and histology..	14	18.5
2. Physiology	4½	6
3. Biochemistry	3½	4.5
4. Pathology, bacteriology and immunology.....	10	13
5. Pharmacology	4	5
6. Hygiene and sanitation.....	3	4
7. General medicine	20	26.5
Neurology and psychiatry		
Pediatrics		
Dermatology and syphilis		
8. General surgery	13	17.5
Orthopedic surgery		
Urology		
Ophthalmology		
Otolaryngology		
Roentgenology		
9. Obstetrics and gynecology.....	4	5
Total	76	100
Electives	24	0

When the teaching conditions demand it, a subject may be transferred from one division to another.

Several of the medical schools now require an internship for graduation. Where it is not obligatory it is strongly urged and graduates should be assisted in securing internships in hospitals approved by the Council on Medical Education and Hospitals of the American Medical Association.

Report of the Council on Scientific Assembly

Dr. James E. Paullin, Chairman, presented the report of the Council on Scientific Assembly, which was referred to the Reference Committee on Sections and Section Work.

Dr. Paullin also presented the following proposed amendment to Section 3, Chapter IX, of the By-Laws, which was referred to the Reference Committee on Amendments to the Constitution and By-Laws:

To amend Chapter IX, Sec. 3 of the By-Laws by adding after paragraph six (6) the following:

"And with the cooperation of the section officers to combine section programs and to arrange such other changes as may seem advisable."

So that when so amended said section will read as follows:

"(6) to arrange the programs for the general meetings of the Scientific Assembly and with the cooperation of the section officers to combine section programs and to arrange such other changes as may seem advisable."

NEW BUSINESS

Resolution on Sulfanilamide

Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Sulfanilamide and its allied products have proved of great usefulness in various streptococcal and other infections of the human body; and

WHEREAS, Its use carries with it toxic symptoms and idiosyncrasies which make it dangerous to human life when the user is not guarded by blood counts and by the supervision of persons with understanding of the drug; and

WHEREAS, the dosage of this remedy is of the greatest importance in obtaining proper results; be it

Resolved, That the medical profession condemn the sale of this drug over the counter and its use by the public, except when prescribed by a physician and taken under his observation.

Resolution Requesting Reconsideration by the Council on Foods of Establishment of Suitable Standards for the Acceptance of Butter

Dr. J. Gurney Taylor, Wisconsin, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The American Medical Association, through its duly elected Board of Trustees, representing the medical profession in each of the several states, in 1929 established a Council on Foods, whose purpose was to create suitable standards for the health claims made in food advertising and to protect the public from unsound, unwarranted, false and fraudulent claims for foods; and

WHEREAS, The Council on Foods of the American Medical Association during these several years has made a valuable contribution in protecting the public from unscientific health claims for foods and has, through its efforts, elevated the standards of advertising for the sale of food products of those commodities that have been granted the seal of acceptance; and

WHEREAS, The public has recognized the value of these efforts and has placed the utmost confidence in the decisions and the work of the American Medical Association through its Council on Foods, which now gives the connotation of a standard of value on those foods which bear the seal of acceptance, and the seal has come to indicate to the public that the medical profession has approved that product and that any product so labeled is a valuable adjunct to the diet of the individual; and

WHEREAS, The seal, once granted to certain butter products, was withdrawn by the Council on Foods without prejudice to such products and without any implication that the nutritional value of dairy products was doubtful, recognizing, on the contrary, that butter and dairy products are valuable components of the daily diet, and thus an unintentional injury may have been done the butter and dairy industry by such withdrawal of the seal of acceptance; therefore be it

Resolved, That the Council of the State Medical Society of Wisconsin, through the regularly elected delegates of the society, call this to the attention of the entire House of Delegates of the American Medical Association at its meeting to be held in San Francisco, June 13 to 17 inclusive, requesting the House of Delegates to request the Council on Foods to reconsider suitable standards for the acceptance of butter and the advertising associated therewith.

Resolution on Traveling Hall of Health

Dr. Howard L. Snyder, Kansas, presented the following resolution, which was referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The successful handling of halls of health and similar exhibits by various state and county medical societies has seemingly demonstrated a vast amount of public interest in activities of this kind; and

WHEREAS, It is believed that visual lay education depicting the progress of modern medicine, the service it is able to offer and the ways and means in which the public may take advantage of that service affords one of the best means for the medical profession to reply to the charges of its present critics; and

WHEREAS, It is further believed that many public agencies, medical schools, boards of health, medical supply concerns and other institutions allied with the practice of medicine would be willing to cooperate with the American Medical Association in the presentation of extensive, efficient and helpful exhibits of this kind; be it therefore

Resolved, That the Kansas Medical Society does hereby suggest and recommend to the American Medical Association that it establish a traveling Hall of Health, including exhibits of all kinds pertaining to public health and the practice of medicine, for display in all parts of the country under cosponsorship with the constituent state associations.

Approved by the House of Delegates of the Kansas Medical Society in annual session on June 12, 1938.

Resolutions Requesting a Study of American Spas

Dr. Carl F. Vohs, Missouri, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, There are some purported spas in America that make exaggerated claims as to their curative properties and that are not conducted on an ethical basis; and

WHEREAS, There is almost a total absence of reliable information on American spas and health resorts; and

WHEREAS, Many American citizens go to European spas when equal or better results might be obtained at American spas with great saving of time, money and inconvenience; therefore be it

Resolved, That this House of Delegates authorize the President of the American Medical Association to appoint a special committee of five to conduct a study of American spas and health resorts to the end that authentic information regarding spas may be available to physicians; and be it further

Resolved, That our delegates be instructed to present this resolution to the House of Delegates of the American Medical Association at the San Francisco session in June 1938.

Recommendations for Establishment of Council on Medical Care

Dr. George Blumer, Connecticut, presented the following recommendations and letter, which were referred to the Board of Trustees:

At a meeting of the House of Delegates of the Connecticut State Medical Society, held June 1, 1938, the following recommendations of the Committee of Twenty on Medical Care were approved and the delegates to the American Medical Association were instructed to present them to the House of Delegates of the American Medical Association at its meeting in San Francisco:

1. That this society request the House of Delegates of the American Medical Association to establish a council of the Association to be composed of individuals especially qualified to deal with the problems of medical care and to be known as the Council on Medical Care.

2. That this society requests the House of Delegates of the American Medical Association to urge that each state medical association appoint a committee on medical care to cooperate with the Council on Medical Care of the American Medical Association and to suggest that each county medical association appoint a committee on medical care to report to and cooperate with the state committee on medical care.

Dr. Blumer also read the following letter in explanation of the recommendations:

June 3, 1938.

Walter R. Steiner, M.D.
646 Asylum Avenue
Hartford, Connecticut
Dear Doctor Steiner:

Your attention is directed to the following resolution passed by the house of delegates of the Connecticut State Medical Society at its annual meeting June 1.

That the Delegates to the American Medical Association be instructed to urge upon the House of Delegates of the American Medical Association the necessity for special qualifications of the members of the proposed Council on Medical Care, and also to urge that this council include representatives from the Bureau of Legal Medicine and Legislation and the Bureau of Medical Economics, and also, as ex officio members, the chairmen of the Council on Medical Education and Hospitals and the Council on Industrial Health and representatives of the United States Public Health Service and the health sections of the United States Department of the Interior.

Copies of this resolution are being sent also to your alternate.

Very truly yours,

CREIGHTON BARKER, M.D.

Resolutions Requesting Council on Foods to Change Its Policy with Respect to the Consideration and Acceptance of Butter

Dr. Fred Moore, Iowa, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, One of the main objectives of the Council on Foods of the American Medical Association is for improvement in the nature of advertising; and

WHEREAS, The Council on Foods has changed its policy and no longer considers and "accepts" butter and other natural dairy products; and

WHEREAS, Since discontinuing its acceptance of butter it has given its seal of acceptance to substitute products such as oleomargarine sold under trade names; and

WHEREAS, This policy of the Council on Foods has encouraged commercial firms to advertise such products as being accepted by the Council on Foods and used and approved by the medical profession at large; and

WHEREAS, This policy of the Council is bringing much criticism on the profession at large from the dairy interests of the country; and

WHEREAS, The medical profession has always advocated the liberal use of natural dairy products in the interest of public health; and

WHEREAS, The profession at large does not want to be held responsible for a policy which discriminates against the natural dairy products in favor of the margarine class of products; be it

Resolved, By the House of Delegates of the American Medical Association, that the Council on Foods be requested to change its policy in such manner as will eliminate this basis for warranted and undesirable criticism of the medical profession and of the American Medical Association; and be it further

Resolved, That the delegates of the Iowa State Medical Society be instructed to present this action to the House of Delegates of the American Medical Association at the annual meeting in San Francisco in June 1938.

Adopted by the house of delegates of the Iowa State Medical Society May 13, 1938.

Proposed Amendments to the By-Laws

Dr. T. R. K. Gruber presented the following proposed amendments to the By-Laws, on instruction from the executive committee of the council of the Michigan State Medical Society, which were referred to the Reference Committee on Amendments to the Constitution and By-Laws:

Insert in Chapter VI, Section 1, of the By-Laws, "except as otherwise hereafter provided for in the By-Laws" after the sentence "All

resolutions or recommendations of the House of Delegates pertaining to the expenditure of money must be approved by the Board of Trustees before the same shall become effective."

Add to Chapter VII, Section 3, of the By-Laws, the following: "(d) Committee on Public Relations."

Add to Chapter VIII, Section 1, of the By-Laws, the following:

"The Committee on Public Relations shall consist of five members each selected for a period of five years by the House of Delegates. The term of office of the members shall expire in succession, one each year, and the House of Delegates shall elect annually one member to fill the vacancy except that in 1938 the House of Delegates shall elect one member to serve one year, one to serve two years, one to serve three years, one to serve four years and one to serve five years. The Speaker of the House of Delegates shall be ex officio member of this committee."

Add to Chapter VIII, Section 3, of the By-Laws the following:

"No appropriation for the expenses of any standing committee for any one year shall be in excess of a maximum or less than a minimum of an amount that may be recommended to the Board of Trustees by the House of Delegates."

Add to Chapter IX of the By-Laws the following new section:

"Sec. 4. The Committee on Public Relations shall have authority to act for the American Medical Association in conference with governmental or lay organizations in matters of public interest, subject at all times to the approval of the Board of Trustees. This committee shall have authority to employ expert and talented professional public relations counsel and assistance as it may deem advisable. Any decision by the Board of Trustees or by the Committee on Public Relations may be revoked by a two-thirds majority of the House of Delegates regularly convened."

Resolutions Requesting the Council on Medical Education and Hospitals to Study the Status of Clinical and Pathologic Laboratories and Other Departments in Hospitals

Dr. Francis F. Borzell, Pennsylvania, presented the following resolutions, which were referred to the Council on Medical Education and Hospitals:

WHEREAS, The American Medical Association has through its House of Delegates and its various bureaus and councils from time to time propounded certain principles of ethics and established standards of relationship looking toward the maintenance of the highest quality of professional service both in private practice and in hospitals; and

WHEREAS, Many of these pronouncements refer specifically to those special branches of medicine involving somewhat unusual relationship between hospitals, institutions and the physician practicing these specialties in the hospital; and

WHEREAS, Certain usages have sprung up which are tending to involve ethical and legal considerations; and

WHEREAS, It would appear to be highly desirable and in the best interests of good medical practice and sound public policy to have certain of the aforementioned pronouncements clarified, codified and in some instances reiterated; be it

Resolved, That the Council on Medical Education and Hospitals be requested to study the status of clinical and pathologic laboratories, radiologic departments and physical therapy departments in hospitals and institutions with a view toward standardizing the relationship of these services to these institutions and when necessary reaffirming principles of ethics involved in these relationships; and be it further

Resolved, That the Council be authorized to confer with such agencies as are deemed necessary to arrive at these conclusions.

Resolution on Motion Picture "Birth of a Baby"

Dr. C. W. Roberts, Georgia, presented the following resolution, which was referred to the Reference Committee on Executive Session:

WHEREAS, At the annual session of the Medical Association of Georgia, held in Augusta, April 26-29, 1938, a committee of the association which was appointed to view and censor the movie film "The Birth of a Baby" reported as follows:

"Your Committee, at the request of Dr. Traylor, after witnessing the presentation of 'The Birth of a Baby' at the Imperial Theater on the morning of April 28, 1938, unanimously agreed that the interest of maternal and child welfare would be advanced by the release of the production. Your chairman, however, feels that there should be some restriction as to the age of those admitted to its presentation. Signed, Joseph Akerman, Chairman," and

WHEREAS, In the discussion of this report in the house of delegates, doubt was expressed as to whether the conditions surrounding the production, release and propagandizing of the picture were in consonance with the policies of the House of Delegates of the American Medical Association, and

WHEREAS, The Medical Association of Georgia, having had submitted to it a request to approve the showing of the film in the movie theaters of Georgia, desired, before taking any action, to have the position of the house established, adopted the following resolution:

"That the recommendation of the Committee representing the Medical Association of Georgia be transmitted to our delegates to the American Medical Association for the consideration of the House of Delegates of that body at the San Francisco session, and that we do not give out any comment to the press at this time"; therefore be it

Resolved, That this resolution be referred to the appropriate reference committee of this House for consideration and recommendation bearing on the issues involved.

Resolution on Fee Schedules

Dr. C. W. Roberts, Georgia, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, state and county medical societies have from time to time, on their own initiative or at the request of others claiming a valid or social interest in the cost of medical services to a particular group, established so-called fee bills on which the contracting persons or groups agree to base charges; and

WHEREAS, Such fee bills often set up without due regard to the equitable interest of the various groups concerned furnish an implement through which exploitation is practiced and abuses encouraged; and

WHEREAS, The necessity for or advisability of such schedules has never been considered by the House; and

WHEREAS, Controversy over the application of such schedules is rife, serving to divert the attention of the contracting persons from the central fact—namely, the quality of medical care—thus reflecting unfavorably on the profession and lending comfort to those critics who charge it with the adoption of trade union methods; and

WHEREAS, It has been the unwritten rule, established by a long line of ethical practitioners both past and present, to adapt charges for medical services to the ability of his patient to pay, untrammelled by fixed community schedules; therefore be it

Resolved, That this device, appearing with increasing frequency, be examined by an appropriate agency of the American Medical Association to the end that the Association may declare itself on certain controversial points, among which are:

(a) The advisability of or necessity for fee schedules in the public interest.

(b) Their ethical or unethical qualities.

(c) Necessity for certain fixed principles to guide constituent units of the Association when and if it is deemed, in the public interest, necessary to adopt such a device, and

(d) Whether such schedules, approved by constituent units of the Association, should or should not provide for elasticity so as to permit of adaptation to wage levels, specialized medical services, variations based on differential costs as between urban, semiurban and rural practice and other related considerations.

Resolution on Revision of Principles of Medical Ethics

Dr. Robert A. Peers, California, presented the following resolution, which was referred to the Judicial Council:

WHEREAS, The Principles of Medical Ethics is the foundation of professional conduct for physicians; and

WHEREAS, Changing times alter tendencies toward interpretation of all ethical rules, although the nature of ethics remains unchangeable; and

WHEREAS, A careful study of the Principles of Medical Ethics makes it apparent that there exists a pressing need for clarification, amplification and codification of these tested and time honored rules of conduct; therefore be it

Resolved, That the Speaker of the House of Delegates appoint a Committee of Five to proceed toward the amplification, clarification, codification and revision of the Principles of Medical Ethics, directing the said committee to report to this House at its session in 1939.

Resolutions on Controlled Animal Experimentation

Dr. Elbridge J. Best, California, presented the following resolutions, which were referred to the Reference Committee on Hygiene and Public Health:

WHEREAS, The knowledge possessed by modern medicine and the remedial measures made available for the prevention, diagnosis and treatment of disease in human beings and in live stock and other domestic animals has been made possible only by controlled, humane and scientific animal experimentation, controlled by medical men, research workers and laboratories; and

WHEREAS, Controlled animal experimentation has uncovered the causes of contamination or blighting of many foods (fruits, vegetables and milk) which makes them dangerous for human and animal consumption; and

WHEREAS, Continuous research, study and investigation of causes and prevention of many human diseases, animal infections and causes for food deterioration are dependent on a continuation of controlled animal experimentation in order that human health and lives, as well as live stock and foodstuffs, may be saved and financial losses be prevented; and

WHEREAS, There are many poorly informed persons now active in an endeavor to enact legislation that would cripple legitimately and humanely controlled animal experimentation so vitally necessary to those scientific men who are seeking the etiology and prevention of conditions that still cause human suffering, that kill fowl, other bird life and animals and that affect the raising of foodstuffs; and

WHEREAS, These persons, commonly known as antivivisectionists, willfully repudiate, ignore and misrepresent the proved facts that have been established by scientific research and study and in their endeavor to secure the enactment of laws prohibiting animal experimentation, which laws and prohibition would cause much human suffering, loss of lives, destruction of animals and foodstuffs and also terminate the studies of scientists and laboratory research workers, persist in their efforts to mislead people; therefore be it

Resolved, That: 1. Controlled animal experimentation is of supreme importance in the study and investigations seeking the cause and cure of factors and conditions that affect the health and cause the death of human beings, animals, fowls, dogs, birds and live stock; and

2. Any and all efforts to restrict or prohibit controlled animal experimentation will cause untold suffering, loss of lives of human beings, animals and live stock and produce an uncalculable financial loss to every community, industry and the commonwealth; and be it further

Resolved, That the American Medical Association condemns the efforts of all who endeavor to cripple scientific research by seeking to obtain the enactment of laws hampering or prohibiting the use of animals in research investigation; and further be it

Resolved, That the House of Delegates recommends that each unit of this Association be urged immediately to undertake the education of the lay public on the need and value of controlled animal experimentation and to expose the unjustifiable and unsupported claims and allegations of those who seek to obtain laws that may hamper or prohibit the humane use of animals in research studies.

Resolution on Recognition of Acting Assistant Surgeons of the Spanish American War

Dr. Elbridge J. Best, California, presented the following resolution, which was referred to the Reference Committee on Legislation and Public Relations:

The House of Delegates of the American Medical Association, now in annual session, reaffirms the statements and convictions as transmitted by the Board of Trustees of the American Medical Association to the House of Delegates at the annual session in Cleveland in 1934, relative to the discrimination and neglect meted out to those men who served as acting assistant surgeons during the Spanish American War, Philippine Insurrection and Boxer Uprising.

WHEREAS, This situation has in no wise been remedied, notwithstanding the efforts and requests of a certain number of these men to bring this neglect to the attention of Congress; and

WHEREAS, Trained nurses who served on contract during this conflict have been declared to have been an integral part of the army and have thus been pensionable since 1922, and all medical officers who served during the World War have a pensionable status; and

WHEREAS, Three fourths of the members of the Yellow Fever Board which rendered a service outstanding in the history of mankind were acting assistant surgeons, one of whom lost his life in the performance of this duty; therefore be it

Resolved, That every officer and agency of our organization, including the legislative committees of our constituent state societies, be empowered and urged to request their respective members of Congress, in justice to themselves and in fairness to this group, to right the wrong and discrimination which has been visited on a body of loyal men who volunteered in an emergency of their government while at war;

Therefore, it is the unanimous sentiment of this body that Congress be requested to give that recognition which has so long been withheld from this group.

Resolution on Hospital Insurance

Dr. Charles H. Goodrich, New York, on behalf of the Medical Society of the State of New York, presented the following resolution, which was referred to the Council on Medical Education and Hospitals:

WHEREAS, The Medical Society of the State of New York on May 9, 1938, adopted revised principles on all matters pertaining to hospital insurance; and

WHEREAS, These principles are known as the restatement of Proposition No. 3 of the Booth Committee Report of 1933 and in substance are as follows:

Preamble: There is in every community a group of people below the "comfort level," on whom the costs of medical care impose a heavy burden. These are self-respecting people of the salaried class in most instances, whose living expenses are met from their weekly earnings. For them the greater part of medical costs comprise charges for hospital and nursing care.

Revision, 1937:

(a) Hospital care shall mean provision of bed, board, general nurse service, customary surgical dressings and medicines, and other facilities of the institution not including medical care as defined in b.

(b) Medical care shall mean: any procedure or service by a licensed physician acting under authority of section 1250 of article 48 of the Education Law of the State of New York.

(c) Hospitals making contracts with organizations, acting under chapter 595 of the laws of 1934—the Insurance Law of the State of New York—shall not implicate themselves with conditions inconsistent with the principles and definitions herewith stated.

(d) The operation of such hospital insurance in any community shall not discriminate against any reputable institution, whether voluntary or proprietary.

(e) Admission of patients for care under the benefits of such hospital insurance shall be only through reference by a private physician. Exemption to this provision shall be made for the exigency of any emergent need.

(f) Certificates of membership in such association shall specifically state that the insurance does not provide for any medical care as defined in b. Actual wording of the certificate to be approved by the local county medical society or societies.

(g) Every hospital insurance plan operating under theegis of this proposition shall develop the details of its operation to conform with such principles and policies as from time to time may be determined by the local county medical society or societies.

(h) When it is so desired by the local county medical society satisfactory representation from the membership of the local county medical society on the board of management of the hospital insurance shall be arranged; and

WHEREAS, On May 9, 1938, the Medical Society of the State of New York directed its delegates to urge adoption of these principles by the House of Delegates of the American Medical Association; therefore be it

Resolved, That the House of Delegates of the American Medical Association hereby approve the principles above stated and that the Council on Medical Education and Hospitals be instructed to refuse or withdraw approval of hospitals that do not comport themselves in accordance with these principles.

Resolutions Requiring of Foreign Graduates Full Citizenship in the United States

Dr. William R. Molony Sr., California, presented the following resolutions, which were referred to the Reference Committee on Medical Education:

WHEREAS, The license to practice medicine and surgery in many countries is limited strictly to citizens of these countries; and

WHEREAS, In addition to holding full citizenship, each applicant is required in several of these countries to show that his medical education was pursued and completed in said countries; and

WHEREAS, Many foreign graduates in medicine and surgery in increasing numbers are seeking admittance to the practice of medicine in these United States; and

WHEREAS, In order to convey adequately to these applicants a full and satisfactory knowledge of the American conception of patriotism and of ethical ideals in medicine, it is necessary that a period of residence be required; therefore be it

Resolved, That in addition to the requirements for foreign graduates, as outlined in a resolution adopted by the House of Delegates for the American Medical Association in 1936, it is highly desirable that an additional requirement of full citizenship in the United States of America be demanded; and be it further

Resolved, That the House of Delegates of the American Medical Association approve the foregoing and that a copy be sent to the properly constituted officers of each examining board of the United States and to the Federation of State Medical Boards, with the request that they consider seriously urgent need for the adoption of such rules and/or legislation necessary to put the purposes of these resolutions into effect.

Resolution on Rockefeller Cancer Control Fund

Dr. Henry C. Macatee, District of Columbia, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, Mr. Willard D. Rockefeller of New York City proposes to establish the "Rockefeller Cancer Control Fund" as a memorial to his mother; and

WHEREAS, Mr. Rockefeller has agreed to assume all responsibility for the establishment of the fund and for making it perpetual by creating an organization for that purpose; and

WHEREAS, The proposed fund is designed to meet the practical needs for the control and treatment of cancer, as distinguished from other foundations to provide for research in cancer; and

WHEREAS, It is proposed that the resources of the fund shall be dispensed through an Advisory Council to be composed mainly of outstanding physicians, and that, in order to provide for the application of funds so dispensed more directly to the needs of the current clinical problems of cancer, funds so dispensed shall be expended through organized, ethical medical channels, by allocation of such funds along three general lines, viz:

First: To provide remuneration to ethical physicians for treatment and care of indigent cancer patients and for specified clinical work.

Second: To furnish equipment and materials to specified clinics and hospitals for cancer work.

Third: For educational purposes; and

WHEREAS, Dr. Edith Se Ville Coale of Washington, D. C., as the friend and physician of Mr. Rockefeller's mother for many years, has been requested by him to serve as trustee of the proposed fund; and

WHEREAS, Dr. Coale, desiring first the approval of the medical society of which she is a member, presented the proposal to the executive committee of the Medical Society of the District of Columbia, which committee, constitutionally acting for the society now in recess, approved the proposed project in principle and directed the delegate of the society to present the plan as herein described for the approval of the House of Delegates of the American Medical Association; now, therefore, be it

Resolved, That the House of Delegates of the American Medical Association, in convention assembled at San Francisco in 1938, approves in principle the creation of the Rockefeller Cancer Control Fund for the purposes indicated by Dr. Edith Se Ville Coale, Trustee.

Resolutions on Program of Public Relations

Dr. Lyell C. Kinney, California, presented the following resolutions, which were referred to the Reference Committee on Legislation and Public Relations:

WHEREAS, The American Medical Association has attempted for many years to appraise and meet the changing problems in the provision and distribution of medical care; and

WHEREAS, The American Medical Association has constantly endeavored to raise the standards of medical practice and has maintained a fixed policy that any necessary changes in medical practice must improve and not sacrifice the quality of medical care; and

WHEREAS, It is the policy of the American Medical Association to endeavor to provide adequate medical care to all the people in this country, and to that end the American Medical Association has offered its facilities and its cooperation to any authorized representative of the government to promote orderly progress and greater efficiency in the provision of medical care; and

WHEREAS, There is a constant and determined attack on the American Medical Association in lay magazines in an effort to discredit the policies of the American Medical Association with the public and the government, to misrepresent the work and ideals of the Association and to mold public opinion against the Association; therefore, be it

Resolved, That the House of Delegates of the American Medical Association direct the Board of Trustees to develop an aggressive and forceful program of public relations in the Bureau of Health Instruction to inform the public and governmental agencies concerning the policy of the American Medical Association with regard to changes in medical practice, and the reasons therefor; and be it further

Resolved, That it is the judgment and the request of the House of Delegates that the Bureau of Health Instruction employ outstanding professional public relations counsel to direct a sustained program for the purpose of presenting to the public the true facts concerning the need for medical care and the position of the medical profession concerning the problems involved.

Resolution on Standards for the Practice of Medicine in Hospitals

Dr. E. H. Skinner, Section on Radiology, presented the following resolution, which was referred to the Council on Medical Education and Hospitals:

WHEREAS, The Board of Trustees of the American Medical Association, in its annual report, has directed attention to certain conditions in these words, "The present situation in the practice of anesthesia, pathology and radiology in hospitals and the potentiality of increasing the number and variety of special medical services controlled by hospitals call for the establishment of a similar ideal standard designed to permit a constant improvement of practice in hospitals"; and

WHEREAS, The said Board in its report has further pointed out that the turmoil between hospitals and national societies of anesthetists, of pathologists and of radiologists cannot continue without harmful effects on the practice of medicine in hospitals; be it

Resolved, That this House of Delegates instruct its Board of Trustees to direct the Council on Medical Education and Hospitals to proceed toward the creation of standards for the practice of medicine in hospitals, such standards to include the requirements for approval of hospitals and the standards which govern the relations between physicians and hospitals.

The meeting recessed at 1:10 p. m. to reconvene Tuesday morning, June 14, at 9:30 a. m.

Second Meeting—Tuesday Morning, June 14

The House of Delegates was called to order at 9:30 a. m. by the Speaker, Dr. Nathan B. Van Etten.

Roll Call

It was moved by Dr. Arthur C. Morgan, Pennsylvania, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, that the House dispense with the roll call.

Presentation of Minutes

On motion of Dr. J. Newton Hunsberger, Pennsylvania, seconded by Dr. John Z. Brown Sr., Utah, and carried, the House dispensed with the reading of the minutes.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, reported that 164 delegates had registered before the close of the meeting of the House on Monday, June 13, and that four delegates had registered since that time, making a total registration of 168. The Speaker declared that this would constitute the roll of the House.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following report of the Judicial Council acting as a reference committee, which was adopted on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried:

The resolution introduced by Dr. Robert A. Peers, California, provides for a rewriting of the Principles of Medical Ethics by a committee of five appointed by the Speaker of the House.

The Principles of Medical Ethics was originally written in 1903 and revised in 1912 by a notable committee consisting of Drs. Frank Billings, Illinois; James E. Moore, Minnesota; A. B. Cooke, Tennessee; Alexander Lambert, New York; and Hubert Work, Colorado. The text today remains the same as the revision made in 1912 with the exception of such amendments as changing times and practices have demanded to meet new conditions. The principles underlying and expressed in the original text have not changed, and amendments that have been made have merely emphasized and clarified the principles with respect to new developments in medical practice. An attempt to rewrite the Principles of Medical Ethics was made at a later date but was abandoned because of failure to produce a more satisfactory text.

The ethics of medicine is stated as it should be in principles of conduct instead of rules. To define and interpret these principles so as to cover every relation of the medical man would be to set up an endless system of rules, regulations and laws approaching in character a criminal code, with its invitation to violation by sophisticated reasoning or through technicality. A rule, regulation or law may be circumvented, but the principle underlying the law cannot be avoided by such means. As occasion arises, amendments will doubtless be made in the future as they have in the past, but these are strenuous times of rapid and radical change and no one can predict the immediate or remote future. The Judicial Council, as your reference committee, recommends that "amplification, clarification, codification and revision of the Principles of Medical Ethics" be postponed.

Respectfully submitted.

GEORGE EDWARD FOLLANSBEE, Chairman.
JOHN H. O'SHEA.
EDWARD R. CUNNIFFE.
WALTER F. DONALDSON.
JOHN W. BURNS.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. Frederic E. Sondern, Chairman, presented the following report, which was adopted by sections and as a whole on motions duly seconded and carried after discussion:

REPORT OF SECRETARY

1. The Secretary reports a gratifying increase in membership of close to 4,000 and in Fellowship of over 2,000, both better records than in the preceding several years, which deserves your commendation.

He directs attention to the steady growth of better organization and field work resulting in helpful contacts with civic and official organizations and the benefits which accrue therefrom. He emphasizes the need for increased interest in scientific work, particularly in the county societies, and suggests that it can be had if the program committees concerned will give greater attention to subjects which tend to awaken and hold the general interest of the membership. In the opinion of your committee this is often due to the practice of leaving the construction of the programs to committees named for this purpose. When the current president concerns himself personally with this matter in the interest of an outstanding administration the results are usually gratifying. Your committee wishes to emphasize that the American Medical Association essentially depends for its strength on the activity of all its constituent state and component county units, and it is therefore incumbent on the state councils to stimulate each and every one of the component county societies to hold regular meetings at which the members should be given the opportunity to renew interest in the scientific and organizational aspects of medicine. Unfortunately there appears to be a deplorably large number of these units that are stagnant, and this condition must be corrected if the Association is to function effectively to your satisfaction.

Your committee asks you to note that the report of the Secretary mentions nothing of the correspondence, using this term in the broad sense, which must result from a membership of close to 110,000 doctors. These countless inquiries, demands, suggestions and complaints, every one of us knows, meet with that invariably prompt, courteous and explicit response which

has made our Secretary so universally admired. We hold this genial, efficient and loyal officer in affectionate esteem, and your committee wholeheartedly endorses his recommendations.

2. The report of the Secretary contains reference to amendments to the Constitution proposed by the Judicial Council, which have had the approval of the Reference Committee on Amendments to the Constitution and By-Laws of the 1937 session of the House.

As these amendments require to be put in proper form for proposed inclusion in the Constitution, they have been referred by the Speaker to the Committee on Amendments to the Constitution and By-Laws for this purpose.

REPORT OF BOARD OF TRUSTEES

3. Resolutions on the Death of Dr. George H. Simmons: The report opens with resolutions on the death of Dr. George H. Simmons, as follows:

WHEREAS, Dr. George H. Simmons rendered distinguished service to the medical profession and to the American Medical Association from 1899, when he became Secretary and Editor, through 1924, when he retired holding the positions of Editor and General Manager; and

WHEREAS, During this period of twenty-five years, his wise leadership, his courage, his progressiveness and his initiative advanced the interests and the status of the Association to heights never before reached by any medical organization; and

WHEREAS, His work for the American Medical Association was characterized by intelligence, unselfishness, honesty and righteousness, and his interest endured to the very end of his days; and

WHEREAS, The Board of Trustees, through its intimate contact with Dr. George H. Simmons in all of these works, is cognizant of the extent to which he gave of himself freely for the good of all; therefore be it

Resolved, That this Board of Trustees spread on its minutes its recognition of his accomplishment, and that it tender to his relatives a suitable copy of these resolutions and its sincere sympathy in their sorrow at his passing.

In addition, your Committee desires to call your attention to the fearless courage of this man's convictions in the interest of creating what has proved to be the outstanding weekly medical publication in the world, in which effort he was often in bitter opposition to prominent medical men, who in consequence were eager to depose him in those early days of his remarkable aims. It was his unflinching adherence, without exception, to the unusually high standard he established which gained him the respect and admiration of the membership and established his work as one of the foundation stones for the glory of our Association. His astute vigilance in the interest of American medical men in the late war is another achievement which deserves your admiration. Your committee also desires to record its regard and sympathy.

4. The report of the Board of Trustees covers more than 130 pages of the Handbook, with many additional actions which have been presented since its publication. Aside from this record of the work of the Board it includes the activities of the various councils, bureaus and departments. All of these show a notable expansion of activities over former years in furthering the best interests of our Association for the ultimate benefit of the public. It is difficult for the reference committees concerned to do full justice to the record of such an extensive collection of endeavors in the short period which elapses between their first meeting and the term set for these reports. Every member of this House should read the original reports in detail in order to be acquainted with the nature and scope of these activities. They are not the expressions of one man or of a selfish clique, but they represent the labor of a relatively large number elected or appointed by you on the basis of their special fitness to investigate and confer and then to express for you the opinions and edicts of organized medicine, subject to your review. Your Board of Trustees is painstaking in its efforts to carry out your instructions in these various fields of endeavor, and its unusually uniform competence should command your respect and your loyalty.

It is further the duty of the members of this House, in the opinion of your committee, to carry away to constituent state and component county organizations at least a summary of the Trustees' report, so that individuals and groups can more understandingly express themselves on the current opinion of organized medicine. In recent time there has been an increasing interest of the public in physicians and their ways and in public health, stimulated by all manner of publicity in newspapers

and in weekly and monthly magazines, some of which is contrary to the best interests of the public. Almost every doctor is questioned by patients and friends on these matters, and his more detailed knowledge of the conclusions of organized medicine tends to safeguard the well-being of the American people.

5. General Work and Business Operations: The gross earnings for 1937, amounting to more than \$1,650,000, with operating expenses under \$983,000, both in advance of the previous year, give you an idea of the magnitude of the operations of your Association. The net income of over \$122,000, of which over \$83,000 represents income from investments and over \$38,000 net operating income, reflects the conservative management.

The details concerning the completion of the Association building and the invitation to all members to visit it are noteworthy. The number of employees, 616, compared with 565 last year and 550 the year before, is further evidence of the increasing activity of the Association, all of which has the approval and commendation of your committee.

6. THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION: That this weekly medical journal is absolutely the leader in its field is generally acknowledged the world over. It is found not only in all medical libraries overseas and in the more representative hospitals as well but also in the offices of the more prominent physicians in all foreign countries. The maintenance of its high standards as well as its progress in new fields as detailed are the result of its outstanding editorial management, headed by the dynamic editor, all of which your committee desires to commend highly. The incorporation into *THE JOURNAL* of the former *BULLETIN*, giving all members the benefit of the more intimate Association news, is particularly valuable at this time of public interest in medical affairs, and your committee desires to voice approval.

Special Journals: The high standards of these publications are also generally recognized. While increased circulation and reduction in cost over outlay continue, the Board of Trustees cautions that there is a limit to the continued absorption of this expense beyond which it considers it unwise to go. While your committee is in complete accord with the Board in the matter of conserving resources in these days of financial uncertainties, it must also be had in mind that the effectiveness and prestige of the Association are in large measure judged by the publications it issues. Our record of continued expansion and faultless production is the envy of national associations elsewhere in the world and the source of much deserved pride. In the opinion of your committee every reasonable effort should be made to continue all the publications, and, if the Board really becomes concerned about the expense burden, thought might be given to the possibility of curtailing some other activities actually less important in maintaining the scientific status of the Association.

Library and QUARTERLY CUMULATIVE INDEX MEDICUS: Your committee wishes cordially to endorse the words of the Board, as follows: "The QUARTERLY CUMULATIVE INDEX MEDICUS, recognized as one of the greatest contributions of the Association to the advancement of medical science, had wider circulation in 1937 than in the previous year, but the cost of publication exceeded income received from subscriptions by the sum of \$42,616.32, slightly more than in 1936 but less than in 1934 and 1935. This publication represents an essential activity of the Association and deserves far more liberal support than it now receives." The value of this publication and its credit to the Association as an outstanding achievement fully justify its cost in the opinion of your committee. Its importance to all scientists the world over might easily interest one of several foundations to donate funds for support, and your committee would suggest the application for a grant to aid at least in the expenses of production and possibly to allow an expansion to include the entire field of medical literature.

The various branches of the library service as detailed in the report are definitely a great aid particularly to those without nearby libraries, and here also the labor and expense involved seem to your committee to be fully justified.

Standard Classified Nomenclature of Disease: The taking over of this notable work by the Association, which will do so much to standardize nomenclature in medical literature, is a commendable step that has the approval of your committee.

HYGEIA: This publication continues to serve the purposes for which it was founded and its increasing success is indicated by the constant gain in circulation. It is an achievement despite the excess of cost over income and the editor deserves congratulation on what he has been able to accomplish in this difficult field.

7. Cooperative Medical Advertising Bureau: Your committee notes with pleasure the service of this endeavor by the participation of thirty-three of the constituent state medical associations. It assures the progress of honest advertising and has the commendation of your committee with the recommendation that efforts should be made to secure the participation of the other state society publications. We learn with regret the loss of Mr. E. W. Mattson as director, the man whose energies had so much to do with the growing success.

8. Motion Picture on Syphilis: This film, produced by the Association in conjunction with the United States Public Health Service, has been a prominent factor in the recent state and national efforts in venereal disease control and represents just another commendable effort of our Association in the interest of public health.

9. Retirement Fund: The establishment of this fund and the plans for its annual enhancement are quite in keeping with modern practice and have the full endorsement of your committee.

10. Medical Patents: The plan of the Board to evolve a method for standardization and coordination in the matter of medical patents has the endorsement of your committee, which joins in the hope that a suitable practice in control may be established. The recommendation to compile a complete list of the holders of such patents and the intention to ask them to attend a national conference to achieve these ends are also commended by your committee.

11. Proposed Change in Name of Bureau of Health and Public Instruction: The recommendation to change the name of this bureau to Bureau of Health Education has the endorsement of your committee, which suggests that the matter be referred to the Committee on Amendments to the Constitution and By-Laws for suitable action.

12. The Division of Drugs, Foods and Physical Therapy: The creation of this division by the Board, composed of the Council on Pharmacy and Chemistry, the Council on Foods and the Council on Physical Therapy, has made it possible to effect closer correlation of the work of these three councils and to enhance administrative efficiency, which action has the endorsement of your committee.

Council on Pharmacy and Chemistry: The important work of this council in the interest of approved therapeutic substances again shows an almost burdensome increase, and the record of its labors has the admiration of your committee. Its publications are both extensive and noteworthy and deserve the full support which they enjoy. These efforts to establish rationalism in therapeutics are most commendable, particularly those concerning vitamins and the endocrine principles.

Council on Physical Therapy: The continued activity of this council in the evaluation and standardization of physical aids in the healing art is praiseworthy and its continued educational program deserves every encouragement.

Council on Foods: It is evident that the efforts of this council to promote truthful advertising of wholesome foods and the necessarily associated labors are a constantly increasing task requiring a large amount of time. In consequence of the stress of this work it was found necessary to conserve the facilities of the Council by accepting only products that seem to require the safeguarding of the public. The need for the setting up of an exempted list should be realized and its object understood. The Council can well exempt products that enjoy competent government control and those of such nature that safeguarding is not necessary.

The Chemical Laboratory: The investigations of the laboratory continue to be of the greatest assistance to the councils requiring this service. Its efficiency and prompt emergency service were strikingly demonstrated in the recent cases of diethylene glycol poisoning. This prompt and thorough service was possible only by a complete organization and a previously established

list of consultants for specific purposes. Your committee desires to express its admiration.

Council on Industrial Health: Your committee commends the manner of formation of this recently established council and records the summary of the Board's report as follows: "The Council on Industrial Health, organized in December 1937, has held two official meetings and has developed a working organization through the appointment of a secretary and the creation of official committees. Articles dealing with various subjects of major importance in the field of industrial medicine are in course of preparation for publication. The Council has adopted official rules and is proceeding as rapidly as possible, with due conservatism, toward the prosecution of plans that have been officially adopted."

13. Bureau of Legal Medicine and Legislation: This report has been referred to the Reference Committee on Legislation and Public Relations.

14. Bureau of Medical Economics: This report also has been referred to the Reference Committee on Legislation and Public Relations.

15. Bureau of Health and Public Instruction: The commendable activity of the Bureau is another function of the Association showing evidences of expansion and ever increasing activity. The dramatized radio programs as a means of public health instruction are a distinctive success, fully satisfying the modern sophisticated audiences, and they have almost completely replaced in popularity the ordinary radio talks, even those by prominent members of the profession. The cooperation of the National Broadcasting Company should be appreciated, and its aid in suggesting the publication and distribution to the schools of a workbook on programs intended for high schools written by Drs. Bauer and Teschner of the Bureau is also noteworthy. The protection of research by the opposition to proposed laws restricting animal experimentation has had the careful attention of the Bureau. The outlook at the moment is serious in Massachusetts and the District of Columbia, particularly on account of the restricting legislation in California. Experiences in New York have demonstrated the desirability of inviting the legislators themselves to visit university and research laboratories in order to learn the truth concerning the experimental use of animals in medical progress. The family physician has been found a most potent aid in convincing the public of the need of animal experimentation in the advance of knowledge not only in human but in animal disease as well. The annual distribution by the Bureau of the pamphlets by Cannon and Drinker and John Dewey to graduating medical students is most desirable.

The cooperation of the Bureau in general and its director in particular with lay organizations has been singularly successful in the methods of public health instruction.

16. Bureau of Investigation: This bureau has continued to function in its well known way, and the receipt and answering of from ten to twelve thousand communications a year indicate how extensive its activities are. Its problems are many and often complex, requiring most astute handling to avoid recriminations.

17. Bureau of Exhibits: The continually increasing scope of the Scientific Exhibit is shown by the presentation of 254 exhibits at the 1937 session of the Association, again a record number. The constant further perfection of the quality of these exhibits has given them a most enviable international reputation. They truly represent one of the noteworthy educational achievements of the Association, of which we may be justly proud. The exhibits dealing with the activities of the Association are likewise outstanding in quality and interest. The fact that they were sent to thirty-three states on 115 separate occasions indicates their educational service, which your committee desires to emphasize and commend.

18. Report of Committee to Study Contraceptive Practices and Related Problems: This report has been referred to the Reference Committee on Executive Session.

19. Report of Committee to Study Air Conditioning: This report on a most important subject should be studied by every physician coming in contact with this problem as demanded by the statement that opportunities for injury to persons sub-

jected to artificial climates do exist. The report represents a very large amount of study and investigation and deserves the gratitude of the Association to those who undertook it. It is evident not only that a problem exists but that its full solution has not yet been found. Your committee would recommend extending to these investigators our appreciative thanks for their able and extensive labor, with the request that they continue this important service in any way they consider of additional value in the interest of public health.

20. Report of Committee to Determine the Value of X-Ray Film with Paper Base as a Substitute for Film with Gelatin Base: This most interesting and instructive report, which deserves your close study, consists of a majority report by three members of the committee and two minority reports by one member each. It represents a large amount of work which deserves your full appreciation. Your committee desires to record its admiration of such educational tasks done gratuitously for the membership of the Association.

21. Report of the Committee on Scientific Research and Report of the Committee on Therapeutic Research: Your committee is in full accord with these many deserved grants made to encourage research. It believes fully in the support of these doubtless qualified individuals, though it is a less usual aid than collective endowment. A survey will demonstrate that the most important discoveries have been the result of individual rather than collective effort, and this is the basis for the commendation of your committee.

22. Request from the American Red Cross for Approval of Its Medical Policies in Disaster: Your committee has considered the request of the American Red Cross for the approval of medical policies in disaster. Dr. William de Kleine, medical adviser of the American Red Cross, and Dr. Herman Baker, president of the Indiana State Medical Association, appeared before your committee. Your committee desires to recommend that you agree with the statement that the primary responsibility for the care of the sick and injured in disaster rests with the local physicians and dentists. The function of the American Red Cross should be that of cooperation with local physicians and dentists by assisting in organizing and directing medical relief work and by providing the needed facilities that are lacking for the emergency.

In general your committee recommends approval of the principles and practices outlined for the handling of medical features of disaster relief, and endorsement of the hope that physicians and dentists, like other community leaders engaged in various phases of disaster relief work, will give their services on a volunteer basis for patients unable to pay. With regard to detailed arrangements for emergency work when volunteer service is not available, your committee feels that a single plan to be operated all over this large country would be impracticable and unwise. However, detailed arrangements for possible emergency could be made by mutual agreement between the American Red Cross and local medical organizations so that a standard might be set in advance.

Respectfully submitted.

FREDERIC E. SONDERN, Chairman.
CLYDE L. CUMMER.
JOHN H. FITZGIBBON.
FRED W. RANKIN.
FELIX J. UNDERWOOD.

Report of the Board of Trustees

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the following report of the Board of Trustees acting as a reference committee, which was presented by Dr. Arthur W. Booth, Chairman, was adopted:

Concerning the recommendations from the house of delegates of the Connecticut State Medical Society that the House of Delegates of the American Medical Association establish a council composed of individuals especially qualified to deal with the problems of medical care, to be known as the Council on Medical Care, and urge each state medical association to appoint a committee on medical care to cooperate with the Council on Medical Care of the American Medical Association and suggest that each county medical society also appoint a committee on

medical care, the Board of Trustees has to report that these recommendations are part of the plan which was originated some months ago, as announced in THE JOURNAL, and which is now in process of becoming effective. The designation of this committee as a Committee on Medical Care will be useful in causing the public to realize that the American Medical Association is concerning itself seriously with this problem.

Telegram from Dr. E. H. Cary, Texas

Dr. Holman Taylor, Texas, reported that he was in receipt of the following telegram from Dr. E. H. Cary, Texas, which the Speaker stated would be spread on the minutes:

Fortunately, with two good kidneys and a first-class heart at 66 and excellent medical care, I am about to conquer the worst fight of my life. Please express in terms of affection as you can so well do the feeling I have for the members and their love and affection which have become a part of me. This untimely illness denied me my greatest annual pleasure, for in the House of Delegates I meet the men who know more about the possibilities of medicine and who, if given a reasonable length of time, will come nearer making a diagnosis of human welfare than any other group.

Messages of Congratulation

On motion of Dr. Carl F. Vohs, Missouri, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the Secretary was requested to send telegrams of congratulations to Drs. E. H. Cary, Texas, and Howard Morrow, Chairman of the Local Committee on Arrangements, on the improvement of their health.

It was requested by Dr. J. Newton Hunsberger, Pennsylvania, that the motion be amended to include the name of Dr. Donald Guthrie, Pennsylvania. The amendment was accepted and the motion was carried.

Report of Reference Committee on Medical Education

Dr. William D. Johnson, Chairman, presented the following report:

1. Resolutions on Medical Practice in Hospitals: The resolutions introduced by Dr. E. H. Skinner, Section on Radiology, Dr. Francis F. Borzell, Pennsylvania, and Dr. Charles H. Goodrich, New York, were taken up and given consideration by the Council on Medical Education and Hospitals acting as a reference committee and will be reported on by that body.

2. Resolutions Requiring of Foreign Graduates Full Citizenship in the United States: The resolutions introduced by Dr. William R. Molony Sr., which in essence express the desirability that foreigners, graduates of foreign institutions, be required to obtain full citizenship in the United States of America before being admitted to practice, meet the full approval of your committee.

3. Report of Council on Medical Education and Hospitals: Your committee has given due and proper consideration to the report of the Council on Medical Education and Hospitals and finds itself in accord with the several recommendations of the Council.

Your reference committee particularly wishes to commend the survey of medical education made by the Council and believes that this study should be so published as to constitute a permanent record of the Association's contribution to this field of professional education. If further funds are required for the final consummation of this project, the committee recommends that proper appropriations be made for this purpose.

Your committee wishes to endorse the report of the Council on Medical Education and Hospitals as a whole, including Supplement A stating the essentials of an acceptable medical school.

Respectfully submitted.

WILLIAM D. JOHNSON, Chairman.
JOHN W. AMESSE.
J. C. FLIPPIN.
MCLAIN ROGERS.
WALTER E. VEST.

On motions, duly seconded and carried, the report of the Reference Committee on Medical Education was adopted section by section and as a whole.

Report of Council on Medical Education and Hospitals

Dr. W. D. Cutter, Secretary of the Council, presented the following report of the Council on Medical Education and Hospitals acting as a reference committee:

The resolutions of Dr. Francis F. Borzell, Pennsylvania, Dr. Charles H. Goodrich, New York, and Dr. E. H. Skinner, Section on Radiology, which were referred to the Council on Medical Education and Hospitals, all dealing more or less with the same subject, were considered together. The proposers of these resolutions, the delegates from the Massachusetts Medical Society, members of the California Medical Association and others met with the Council to express their views concerning the problems that concern the practice of medicine in hospitals by radiologists, pathologists and anesthetists. These problems have been rendered more acute by the rapid extension of systems of group hospital insurance within the last few years. The Council believes that these problems are of vital concern to the medical profession; that unwise decisions at this time may lead to consequences that would be disastrous to physicians and to the public alike, and that, therefore, a serious study should be made of existing relationships between hospitals and the physicians practicing therein, especially in the departments of anesthesia, radiology, pathology and physical therapy, with a view to standardizing the relationship of these services to the hospital and, where necessary, of reaffirming the principles of ethics involved.

The Council recommends that it, jointly with the Bureau of Medical Economics, be authorized to undertake these studies and to confer with other interested agencies, in order that it may be in a position to establish ethical standards for the practice of medicine by physicians holding positions in hospitals and to prevent the exploitation of either the public or the profession. If during this study it is revealed that hospitals registered and approved by the Council are exploiting the public or the profession, such approval may be revoked.

Respectfully submitted.

RAY LYMAN WILBUR, Chairman.
JOHN H. MUSSER.
FRED MOORE.
FRED W. RANKIN.
CHARLES GORDON HEYD.
W. D. CUTTER, Secretary.

It was moved and seconded that the report of the Council on Medical Education and Hospitals be adopted.

Dr. R. W. Fouts, Nebraska, moved that the word "may," the third word from the end of the report, be changed to "shall," and the motion was seconded by Dr. Francis F. Borzell, Pennsylvania. After discussion by Dr. Olin West, Secretary, this amendment was laid on the table on motion of Dr. A. A. Ross, Texas, seconded by Dr. Robert F. Barber, New York, and carried.

Dr. W. H. Seemann, Louisiana, moved that the report of the Council on Medical Education and Hospitals be adopted, and the motion was seconded by Dr. John Z. Brown Sr., Utah, and carried after discussion.

Report of Committee on Legislative Activities

Dr. F. S. Crockett, Indiana, in the absence of Dr. E. H. Cary, Chairman, presented the following report of the Committee on Legislative Activities, which was referred to the Reference Committee on Legislation and Public Relations:

The Committee on Legislative Activities regrets that owing to the present serious illness of Dr. E. H. Cary, Chairman, this report covers only a portion of committee activities.

Concerning matters of general interest relative to legislative activities in Washington, the committee found no occasion to visit the Capitol. During the year Dr. E. H. Cary and Dr. C. B. Wright from time to time, while there, found opportunity to keep in close touch with the legislative and administrative branches of the government. Extensive correspondence by the committee secretary, Dr. R. L. Sensenich, is evidence of increasing interest by the profession generally.

The Veterans' Administration is now equipped with a total of eighty-one facilities having a bed capacity of 49,558. These

are divided into neuropsychiatric, twenty-six, with 25,648 beds; general medical and surgical, forty-three, with 18,453 beds; tuberculous, twelve, with 5,457 beds. Number of admissions in 1937: neuropsychiatric, 22,183; general medical and surgical, 108,274; tuberculous, 11,080; total, 141,537.

Bills pending in Congress reported in February of this year, proposing new instruction and additional beds to existing facilities, present a rather startling array: neuropsychiatric, 2,194; general medical and surgical, new hospitals, twenty-one, with 5,100 beds and other additional beds, 2,649; tuberculous, 400 beds.

It is worthy of note that this continued and recurring demand for increased building of hospital facilities does not represent the desire of any large group or of the Veterans' Administration. In all probability very few of these bills will be reported out of committee.

Committee activities have included meetings with groups having medical problems or the activities of which might create situations of interest to the profession. The committee participated in the meeting last December of the American Public Health Association, the U. S. Public Health Service and members of the Board of Trustees, where the problem of medical care for the indigent and those whose income is below the subsistence level was considered.

Last December the committee was represented at the annual convention of the Associated Women of the American Farm Bureau Federation. This group has a membership of 475,000 and is affiliated with the American Farm Bureau, which has a membership of over a million. Organized agriculture as represented by this group continues to seek better medical and hospital care for those living in rural districts. Three years ago there was a strong demand for indorsement of measures providing medical care through governmental agencies. Assurances of sympathetic cooperation on the part of our organization and the study of the whole problem succeeded in obtaining a more conservative attitude by this Farm Bureau affiliate.

Since then your committee, with the assistance of Dr. R. G. Leland, Director of the Bureau of Medical Economics, has sought factual data in support of this objective.

Evidence of continued interest on the part of the Farm Bureau women is shown by the following resolution, adopted at their last convention:

HEALTH

A. We express our confidence in the medical and dental professions and appreciate the services rendered in the pursuit of positive health for rural America. However, we realize that the needs in medical care, dental care and hospitalization in rural districts are not provided for adequately because of prohibitive costs;

We therefore request that the medical association join with us in a plan to further the distribution of their services by allowing county medical boards and individual doctors the right to cooperate with groups of rural people in securing adequate health services at a cost commensurate with income of rural families.

B. We urge that the A. F. B. F. support the principles of group medicine and hospitalization on a cooperative basis.

C. We declare our willingness to cooperate with recognized public health agencies in the pursuit of positive health standards, rural and urban.

Local Farm Bureaus are at present negotiating with hospital associations to obtain benefits under the group hospitalization plan, Missouri, Minnesota and Arkansas having reported such activities. In Los Angeles the local Farm Bureaus have contracted with a large medical group for both hospital and medical care on a monthly prepayment plan. According to a report this arrangement has proved very satisfactory to these farm women who find it difficult to understand why such a prepayment plan, to them so desirable, cannot be extended to other localities.

While the problem is too complex for early solution because it is largely local in scope, it is hoped that, through continued cooperation with this group, further study of the many problems involved will result in improvement of medical service to rural areas.

This committee in previous reports has called attention to the necessity of local or county societies giving consideration to the problem that is present in their community. The statement is repeatedly made that charges made in rural communities are

still based on mileage in such a manner as to exceed the charges made for like service in urban communities. This may not apply to all rural districts but still constitutes a matter of major complaint. Solution is not to be found in resolution by this House or the headquarters office of the Association but must be obtained through county societies dealing directly with their farm communities.

Respectfully submitted.

E. H. CARY, Chairman.

J. H. J. UPHAM.

Report of Reference Committee on Hygiene and Public Health

Dr. H. B. Everett, Chairman, presented the following report:

1. Resolution on Traveling Hall of Health: While your reference committee favors such advancement enterprises as are described in this resolution, it seems best to recommend that the resolution be referred to the Board of Trustees for consideration and with authority to develop such exhibits if in its judgment they may be produced and managed without undue expense to the Association.

2. Resolutions on Controlled Animal Experimentation: Your reference committee recommends the adoption of these resolutions with slight changes in wording.

3. Resolutions with Respect to Consideration of Butter by Council on Foods, submitted by Dr. J. Gurney Taylor, Wisconsin, and Dr. Fred Moore, Iowa: Your reference committee finds merit in both these resolutions and recommends that the House of Delegates request the Council on Foods to reestablish suitable standards for the acceptance of butter and the advertising associated therewith, and also recommends that the House of Delegates request the Council on Foods to scrutinize carefully the advertising of accepted brands of oleomargarine or butter substitutes to the end that no improper or extravagant claims of nutritional value be associated with the printing of the seal of acceptance of the Council on Foods of the American Medical Association.

4. Resolutions Requesting a Study of American Spas: Your reference committee, before dealing with these resolutions, ascertained from Dr. Morris Fishbein, Editor of THE JOURNAL, that a list of resorts is now being compiled at the office of the American Medical Association. Your reference committee, therefore, sees no advantage in acting on these resolutions.

Respectfully submitted.

H. B. EVERETT, Chairman.
CHARLES H. GOODRICH.
J. F. HASSIG.
JOSEPH F. SMITH.
CHARLES S. SKAGGS.

On motion of Dr. Everett, seconded by Dr. Felix P. Miller, Texas, and carried, the first section of the report of the reference committee was adopted.

The second section of the report of the reference committee was, on recommendation of Dr. Arthur J. Bedell, Section on Ophthalmology, referred back to the reference committee for revision, for deletion of many repetitive expressions in the resolutions and for making a further report.

Dr. Everett moved that the third section of the report of the reference committee be adopted. The motion was seconded by Dr. A. T. McCormack, Kentucky, and carried after discussion.

It was moved by Dr. Everett, seconded by Dr. A. T. McCormack, Kentucky, and carried, that the fourth section of the report be adopted.

On motion of Dr. Everett, seconded by Dr. A. T. McCormack, Kentucky, and carried, the report of the reference committee was adopted as a whole with the exception of the portion of the report that was referred back to the reference committee.

Report of the Reference Committee on Miscellaneous Business

The Vice Speaker, Dr. H. H. Shoulders, took the chair and called for the report of the Reference Committee on Miscellaneous Business.

Dr. Fred Moore, Chairman, presented the following report:

1. Resolution on Rockefeller Cancer Control Fund: Your committee approves of the principles suggested, provided the majority of the Advisory Council is composed of physicians who are members of the American Medical Association and provided, further, that the work be limited to the treatment of cancer as indicated in this resolution.

2. Resolution on Sulfanilamide: Your committee approves the resolution presented by Dr. Burt R. Shurly, Section on Laryngology, Otolaryngology and Rhinology, regarding the sale and use of sulfanilamide.

3. Resolution on Fee Schedules: This resolution, presented by Dr. Charles W. Roberts, Georgia, is very broad in its scope and involves all the questions which may develop from consideration of fee schedules. The resolution requests that the subject be "examined by an appropriate agency of the American Medical Association, to the end that the Association may declare itself on certain controversial points." Your committee believes that such a study should be made and recommends that this resolution be referred to the Bureau of Medical Economics for the conduct of such study. It further recommends that the Bureau of Medical Economics be instructed to submit its report to this House of Delegates at the next annual session.

Respectfully submitted.

FRED MOORE, Chairman.
E. S. HAMILTON.
WALT P. CONAWAY.
F. S. CROCKETT.
E. L. HENDERSON.

On motions of Dr. Moore, duly seconded and carried after discussion, the report of the reference committee was adopted section by section and as a whole.

Address of Past President Hubert Work

Dr. N. B. Van Etten, Speaker, presented to the House Dr. Hubert Work, Past President of the Association, who addressed the House as follows:

Mr. Speaker and Members of the House of Delegates:

When the Sergeant-at-Arms, Holman Taylor, arrested me in the corner and confronted me, the only thing I could think of to say was to cry out "Does no one here know Rip Van Winkle?" But some one evidently did and I thank you, Mr. Speaker, for the opportunity to look these men in the face again. It recalls many old and many pleasant memories. For four years I stood before you and as I remarked to a friend when a motion was defeated recently, "They can't put it over the House of Delegates, because I tried it for four years and never succeeded."

Report of Reference Committee on Amendments to the Constitution and By-Laws

The Speaker, Dr. N. B. Van Etten, resumed the Chair.

Dr. Henry A. Luce, Chairman, presented the following report:

REPORT OF JUDICIAL COUNCIL

Your Reference Committee on Amendments to the Constitution and By-Laws has studied with pride the report of the Judicial Council and commends the activities of the Judicial Council for its luminous and splendid work as evidenced by its clearcut and forcible report, as illustrated under the headings "Discipline by Resolutions," "Study of Constitutions and By-Laws," "Rental of Radium," "Physicians and Cultists" and "Finality of State Action."

Association of Physicians and Cultists: Your committee wishes to endorse emphatically that part of the report of the Judicial Council pertaining to the association of physicians and cultists and to state that it is the feeling of your committee that this should be incorporated as a firm principle governing the course of action of physicians generally.

Your committee further suggests that this part of the report is sufficiently important to be brought to the attention of the

officers of the various state medical associations, with the request that this matter be brought to the attention of their respective general assemblies.

Rental of Radium: There was an objection to the last sentence in that paragraph pertaining to rental of radium, which the committee considered most carefully. After due consideration of the matter, your committee feels that the phraseology should remain. Any exceptions to the general principle involved would defeat its purpose.

Study of Constitutions and By-Laws: In view of the rapidly changing conditions of medical practice, that portion of the report of the Judicial Council dealing with the study of the constitutions and by-laws is of utmost importance. The recommendation made in the report regarding the supervision of various types of medical care by the state society is especially to be stressed as is the fact that the constitutions and by-laws of the component county societies should conform with those of the state society.

It is further recommended that the constituent state organizations consult with the Judicial Council in such cases when changes in the constitutions are deemed necessary.

PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

Your committee approves the adoption of the following recommendation from the Chairman of the Council on Scientific Assembly:

Amend Chapter IX, Section 3, of the By-Laws by adding to the end of item (6) the following: "and with the cooperation of the section officers to combine section programs and to arrange such other changes as may seem advisable," in order that when so amended Chapter IX, Section 3, item (6) will read as follows: "(6) to arrange the programs for the general meetings of the Scientific Assembly and with the cooperation of the section officers to combine section programs and to arrange such other changes as may seem advisable."

Change in name of Bureau of Health and Public Instruction: That matter referred to the committee relative to the proposed change in name of the Bureau of Health and Public Instruction to the Bureau of Health Education has been approved by your committee, which recommends that Chapter VI, Section 2, be amended to read as follows:

SEC. 2. TO ESTABLISH BUREAU OF HEALTH EDUCATION.—The Board of Trustees shall establish a bureau, to be known as the Bureau of Health Education, to carry on such activities in the field of health and the dissemination of information in relation thereto as the House of Delegates may direct or the Board of Trustees, in the absence of such directions, may determine. (As adopted, 1923, and amended, 1938.)

Your committee recommends to the House of Delegates the adoption of the proposed amendment to the Constitution as set forth in the following resolution submitted at the annual session of the Association held in Atlantic City in 1937 by the Judicial Council:

WHEREAS, The Constitution and the By-Laws refer to the election annually of a President and President-Elect when in fact only a President-Elect is elected; and

WHEREAS, No provision is made in the Constitution and By-Laws for a succession in office in case of death or disability of the President-Elect; be it

Resolved, That article 6, section 2, of the Constitution be amended to read: "(a) The President-Elect shall be elected annually. He shall serve as President-Elect until the annual session of the Association next ensuing after his election and shall become President on his installation in the course of that session, serving thereafter as President until the next following annual session and the installation of his successor. If the President-Elect dies, resigns or, in the judgment of the Board of Trustees, confirmed by the House of Delegates, is permanently disqualified for the performance of the duties of his office by any just cause, the Vice President shall become President-Elect and in due course succeed to the presidency, with all of the prerogatives and duties pertaining to that office, as fully as if elected to it in the first instance: Provided, however, that the President-Elect who is elected at the annual session of the Association in 1937 shall, notwithstanding his election as such for the period of one year only, be installed as President in the course of the session in 1938 and continue as such until the session in 1939 and the installation of his successor.

(b) A Vice President, a Secretary, a Treasurer, and a Speaker and a Vice Speaker of the House of Delegates shall be elected, each to serve for one year and until his successor is elected and installed: Provided, however, that in event of the death, resignation or removal, or of the permanent disability of the President-Elect as determined by the Board of Trustees, the Vice President shall succeed to the office of President-Elect and in due course to the office of President, notwithstanding the fact that he was in the first instance elected as Vice President for one year only

Changes in By-Laws proposed by Michigan State Medical Society: Relative to the proposed changes in the By-Laws as introduced to the House at the request of the executive committee of the Michigan State Medical Society and referred to this committee, your committee feels that the motivation of this proposal is comparable to that which led to the introduction of the resolutions presented by Dr. Lyell C. Kinney, California. Your committee requests permission to delay the report on this particular portion until the Thursday meeting of the House of Delegates, and requests that the House authorize the committees to which these resolutions and changes were referred to meet in a joint meeting for the determination of the group thinking on this important matter.

Respectfully submitted.

H. A. LUCE, Chairman.
HERBERT L. BRYANS.
GEORGE P. JOHNSTON.
CHARLES J. WHALEN.
RAYMOND L. ZECH.

On motions of Dr. Luce, duly seconded and carried after discussion, the report of the reference committee was adopted section by section.

On motion of Dr. Luce, seconded by Dr. J. Gurney Taylor, Wisconsin, and carried, the amendments to the Constitution and By-Laws as recommended in the report of the reference committee were adopted unanimously.

Dr. Luce moved that the House authorize the respective committees referred to in the section of the report of the reference committee referring to the changes in the By-Laws proposed by the Michigan State Medical Society to meet jointly and bring in a combined report. The motion was seconded by Dr. John Z. Brown Sr., Utah, and carried.

Report of Reference Committee on Reports of Officers

The Vice Speaker, Dr. H. H. Shoulders, took the chair and called for the report of the Reference Committee on Reports of Officers.

Dr. J. N. Baker, Chairman, presented the following report:

Your Reference Committee on Reports of Officers, after reviewing these addresses to the Association, has pleasure in submitting the following report:

1. The Address of the President: The President, after an arduous year of service to the Association in visitation of state and district medical groups throughout all sections of the country, crystallizes, in concrete fashion, certain impressions gained through these many contacts.

He first directs attention to the avidity of the general membership for self improvement in medical knowledge, as manifested by the ever mounting number of scientific medical societies. He wisely points to the need for caution, on the part of purely scientific medical groups or their chosen officers, in any pronouncement on questions of medical polity affecting the entire profession. Your committee feels that the official machinery for organized medicine through which all questions of national policy and of ethics should rightfully clear, is the House of Delegates of the American Medical Association, and that it is incumbent on this body to preserve the truly democratic spirit in which this organization has been conceived, alike in its own deliberations, in the behavior of its chosen officials and in the conduct of its official mouthpiece—*THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*. In these troublous times of social unrest there is real need, on organized medicine's part, for a tolerant attitude of openmindedness, which should ultimately lead to less internal discord and to a more wholesome appreciation, on the public's part, of the high ideals and principles of our profession.

Other impressions received through the President's many contacts have been an awakened interest within the profession in all socio-economic problems now confronting society, together with an avowed and determined purpose to see to it that organized medicine proves no laggard in contributing a full share toward their solution.

The President closes his thoughtful address by making an earnest plea for full and whole-hearted cooperation by the entire medical profession in the nationwide campaign now in the offing against that ubiquitous enemy of mankind, syphilis.

2. Address of the President-Elect: The President-Elect, without wastage of time or words in felicitous salutation, embarks forthright on a brief yet lucid presentation of two topics of paramount concern to the members of this organization.

The first is the need, in these critical times of social instability and readjustment, for the preservation of the ethical principles of medical practice, evolved through centuries of mankind's murky gropings to higher intellectual and social levels. These intangibles, while difficult of comprehension by the lay mind, constitute real and vital things and are the heritages and traditions of an ancient and honorable profession. He views with enthusiasm and deep concern the nationwide survey of medical needs now being prosecuted by state and county medical societies under the leadership of the American Medical Association. Out of such a study, seriously and earnestly made by doctors, your President-Elect feels, should come a wealth of material bearing on the social and economic factors within a given state or community, which, when known, should lead to a clearer definition of the problem of medical needs and to sounder recommendations on the part of the medical profession in meeting existing needs. It is further pointed out that while physicians continue to contribute freely of their time and talent to charity—estimated to be approximately a million dollars daily—yet the indigent and semi-indigent medical load continues to grow apace, and that the information gleaned from this survey should lead to plans for solution in consonance with the basic principles of sound medical practice.

The second topic stressed by the President-Elect is that of graduate medical education, both for the perfection of specialists in the several fields of medicine and for the continuing improvement of the general practitioner, the aggregate of whom constitutes medicine's first line of defense. He commends the untiring efforts now being put forth in this field both by the state and by county medical societies, guided and stimulated by this Association, and makes an urgent plea for an ever widening expansion of these refresher courses for physicians so circumstanced as not to be able to procure these advantages in the larger teaching centers.

3. Address of the Speaker: The Speaker, by way of introduction and in order to point the moral for the need of knowing one's business, lifts from Aesop's fables the story of the elephant which attempted to play the part of a mother bird.

Then follows a series of searching and pertinent questions over which every physician will do well to ponder: "Are we properly mixing our sociology with our medicine?" "Are we really altruistic or are we dominated by a mass of individual economic desires?" "Do we, or do we not, correctly interpret the opinions of the medical profession of the United States?"

Having propounded these and other timely questions, he points to the great responsibility resting on this body, the House of Delegates, which constitutes the legal machinery and which serves as the official mouthpiece of orthodox medicine throughout the nation. "On your shoulders," he says, "rests the fate of American medicine."

He then makes an earnest plea that this body assume a statesmanlike attitude toward all the manifold problems presented by modern-day society and that it dedicate itself anew in efforts to aid in their solution.

Your reference committee feels that the counsel contained in this message is so timely and of such importance, not only to the members of this body but also to every practicing physician that it recommends that the matter be given a conspicuous place in *THE JOURNAL OF THE ASSOCIATION*.

Your reference committee finds that these addresses, while brief and concise, are scholarly, timely and of a high order of excellence, and commends them to the careful reading of the Association's entire membership.

Respectfully submitted.

J. N. BAKER, Chairman.
ELDRIDGE J. BEST.
BEN R. McCLELLAN.
RICHARD H. MILLER.
ARTHUR C. MORGAN.

On motions of Dr. Baker, duly seconded and carried after discussion, the report of the Reference Committee on Reports of Officers was adopted section by section and as a whole.

NEW BUSINESS

Resolution on Teaching in Schools of Chiroprody

Dr. G. Henry Mundt, Illinois, presented the following resolution, which was referred to the Judicial Council:

WHEREAS, The American Medical Association has declared it unethical for members to teach in schools of optometry; and

WHEREAS, In the annual report of the Judicial Council of the American Medical Association we find these words: "Teaching in cultist schools and addressing cultist societies is even more reprehensible, for such activities give public approval by the medical profession to a system of healing known to the profession to be substandard, incorrect and harmful to the people because of its deficiencies"; and

WHEREAS, Members of the American Medical Association are now serving on the faculties of schools of chiroprody; therefore be it

Resolved, That the House of Delegates of the American Medical Association deems such practice unethical.

Resolutions on Services of Section Delegates

Dr. Charles W. Roberts, Georgia, presented the following resolutions, which were referred to the Reference Committee on Miscellaneous Business:

WHEREAS, There are multiplying evidences of the zeal exemplified by the delegates from the sections in preserving and interpreting to the various special societies in which they hold membership the policies and principles of the House of Delegates of the American Medical Association; and

WHEREAS, There is need in this critical period for wide recognition of the fact that the House of Delegates of the American Medical Association is the only body in this country entitled by election on a democratic basis to speak in the name of American medicine on the questions of social, economic, ethical and clinical relations of the doctor to the delivery of medical care; and

WHEREAS, These noteworthy activities of the delegates for the sections in the aforementioned fields are worthy of emulation by all delegates in their relations to medical societies composed of but not sponsored by organized medicine; therefore be it

Resolved, That the House of Delegates express to the delegates from the sections its appreciation of their constructive services to the Association; and be it further

Resolved, That they and all other delegates be encouraged to continue their efforts to the end that the quality of medical service to the American people may be preserved.

Resolution Dealing with Alcoholic Intoxication

Dr. Thomas F. Thornton, Iowa, presented the following resolution, which was referred to the Reference Committee on Miscellaneous Business:

WHEREAS, The medical and legal professions, the courts and the public have been repeatedly unable to determine legally the sobriety or the degree of intoxication of individuals accused of violating the established rules and laws of safety; and

WHEREAS, Such inefficient methods of clinical and laboratory diagnosis and legal procedures are unscientific and a direct cause of much unnecessary expense, litigation and suffering and directly encourage minor verdicts for major offenses; therefore be it

Resolved, That the executive council of the Iowa State Medical Society ask the cooperation of the American Medical Association in a study looking toward the determination of definite, legally acceptable, scientific clinical and laboratory tests for alcoholic intoxication by

1. Studying and recommending such clinical and laboratory tests as have proved successful in Europe and in this country;
2. Prescribing a standard of qualifications of the persons, laboratories and hospitals taking and making these tests;
3. Suggesting such legislation as may be necessary to establish these clinical and laboratory tests;
4. Coordinating the medical and legal profession with the various police agencies and safety councils in this activity; and
5. Suggesting adequate financial support from such funds as may be available from the liquor license tax or elsewhere to supply equipment necessary to taking and making such tests.

Resolution Approving in Principle the Indiana Plan of Health Education and Preventive Medicine

Dr. H. G. Hamer, Indiana, presented the following resolution, which was referred to the Reference Committee on Medical Education:

WHEREAS, A pressing need exists for the development of a national policy on the part of organized medicine to bring the benefits of preventive medicine to all the people; and

WHEREAS, The medical profession, through its local county and state medical societies, already has made tremendous progress in developing programs local in scope; and

WHEREAS, A program of professional and lay health education is now functioning successfully in Indiana; and

WHEREAS, The profession in controlling tuberculosis, malaria, typhoid, diarrhea, yellow fever, puerperal sepsis and other infectious diseases has been largely responsible for the present favorable morbidity and mortality rates; and

WHEREAS, It is essential to make preventive medicine an integral part of organized medicine and individual private practice; and

WHEREAS, In order to put into immediate action at this session of the House a suggestion so ably stated on numerous occasions that "the attention of state and county societies should be drawn to the opportunity of assuming a definite leadership in the respective states and counties and directed with the best ideals of medicine and the best interests of the public"; therefore be it

Resolved, That the House of Delegates of the American Medical Association approves in principle the Indiana plan, a copy of which follows, of health education and preventive medicine and directs the Bureau of Health Education of the American Medical Association to bring this plan to the attention of the medical profession and the lay public through all available channels.

TWO BIRDS WITH ONE STONE (THE TWO BIRDS "DISEASE" AND "SOCIALIZED MEDICINE")

INDIANA SUGGESTS A

WORKABLE PLAN

TO PROTECT THE HEALTH OF THE PEOPLE OF THE UNITED STATES

AN ANTIDOTE FOR STATE MEDICINE

Frequently today the physician finds articles in the press questioning his efficiency and his methods of practice. Such articles accuse him of ignoring preventive medicine in his daily work. He is bewildered and defensive in his attitude, for he feels that he is doing his job well. Even superficial observation will disclose the marked drop in death rate as a result of measures instituted by the medical profession in controlling tuberculosis, malaria, typhoid, diarrhea, yellow fever, puerperal sepsis and other infectious diseases. Preventive medicine is now being practiced by all physicians as private practitioners to some degree. In many parts of the state, county medical units have a definite program. The time is ripe to correlate these scattered activities, survey our local situations, and acquaint the public with the extent of this phase of our work.

Many phases of preventive medicine have advanced by stimulation from outside groups. Drives have been sponsored with much misunderstanding. Preventive medicine has now reached its maturity and should be utilized to the fullest by organized medicine and by the individual doctor. It is futile for one county or state to try to promote this alone. Disease and disaster are not aware of state borders. A national policy on the part of organized medicine is needed now.

Too long have we kept our light under a bushel. It is time to take the offensive. The amount of preventive medicine can be increased by the private practitioner with definite benefit to his community and to himself, and the public will be made to realize that American Medicine is pliable enough to continue as an individualistic enterprise.

Throughout the ages, medicine has adapted itself to social changes. We are now in one of those states of changing social customs and aspirations. The American public looks to organized medicine for leadership. Prevention of disease, early recognition of defects and diseases, reduction of hazards and prolongation of life are the important functions of a physician.

In Indiana we have visualized preventive medicine as a wheel with each spoke representing some important phase. Each phase is featured as a "Topic of the Month" in the *Journal of the Indiana State Medical Association* and is announced or discussed in each county medical society the month the subject is featured. The topic of the month is given support in the press and is discussed by speakers before medical and lay groups.

TOPICS OF THE MONTH

January—Formulation of Plan.

February—Syphilis.

March—Pneumonia.

April—Diphtheria.

May—Maternal and Child Health.

June—Crippled Children.

July—Highway Accidents.

August—Occupational Diseases.

September—Annual 'Physical' Examinations and Heart Disease.

October—Conservation of Eyesight.

November—Tuberculosis.

December—Smallpox.

PURPOSE

To promote aggressive leadership by Organized Medicine in Prevention of Disease and early detection of defects.

To incorporate preventive medicine as an important phase of private practice and of county medical activity.

To promote a National Health Program with emphasis on Prevention of Disease sponsored by the American Medical Association with due regard for local situations.

Our modern age demands cooperative efforts by organized medicine to distribute modern medicine.

DIVIDENDS OR RESULTS

1. Create good will and public approval.
2. Raise general standard of medical practice.
3. Prevent many deaths and much suffering.
4. Give a better ordered life for the doctor.
5. Give a steadier income for the doctor.
6. Intelligent defense against disease is our best defense against government encroachment.

ALTERNATIVE

Noisy and aggressive lay groups will seize leadership and we will trail behind, cloaked with heavy governmental supervision.

SYPHILIS

"NO BABY BORN WITH SYPHILIS IN INDIANA BY 1940"
Can be controlled by:

1. Premarital examination including blood test.
2. Blood test early in every pregnancy.
3. Making good treatment available to all.
4. Good laboratory service available to all.
5. Reporting of new cases by name or number to health department.
6. Tracing contacts by trained social investigators.
7. Free distribution of drugs for medically indigent patients.
8. Isolation of infectious, noncooperative cases.
9. Making provision for infectious transient or itinerant.
10. Cooperation of private physicians and public clinics.
11. Developing and popularizing a minimum standard of treatment for early syphilis.
12. Continuing the educational program among medical and lay groups.
13. Helping the Negro solve his syphilis problem.
14. Spinal puncture on every treated case.
15. Spending the syphilis dollar where it counts.

PNEUMONIA

1. Leadership by the medical profession in developing a complete pneumonia program for all the people.

2. Recognition by the physician of the importance of early diagnosis and early treatment of pneumonia and the use of life-saving types of serum.

3. Development of facilities so that typing may be done within four to six hours.

4. Appointment of committees by state and county medical societies for special studies in pneumonia.

5. Adequate nursing care for home cases.

6. Development of adequate hospital facilities.

7. Education of the public as to the gravity of the whole pneumonia problem, and the fact that the common cold often is an antecedent for pneumonia.

8. Education of the public as to what may be expected if pneumonia is properly handled.

9. Formation of serum "banks" in order to supply serum immediately and free to the indigent or on proper credit to those who are solvent but incapacitated.

10. Try to lower the cost of present forms of treatment.

11. Usual well established supportive treatment indicated in addition to serum treatment.

12. Teach the physicians generally the importance of early typing of every suspected pneumonia.

DIPHTHERIA

1. Immunization of every child at 1 year of age by family doctor.

2. Accomplished by following plan:

When child is 1 year of age local health officer sends a double postcard to the parents stating that it is the judgment of organized medicine and health authorities that now is the time to immunize the child against diphtheria and to see the family doctor at once. When the injections have been completed the doctor returns the second half of the card to the health officer.

If immunization of the child is unpractical from the standpoint of (1) finances, (2) moved away, (3) death of child, (4) religious objection of parents, the parents are asked to check and return. The medically indigent are handled according to the customs of the community.

3. When child enters school he receives a Schick test or another injection of toxoid.

No Drives—No Misunderstandings—Constant Pressure

MATERNAL AND CHILD-HEALTH

"SAFE MATERNITY—HEALTHY CHILDREN"

1. Good antepartum care available to all.
2. Nursing assistance at home deliveries.
3. Continued study of the causes of maternal and infant mortality by organized medicine.
4. Inquiry as to cause of each individual death by the state committee and hospital staff.
5. Immunization program for all children.
6. School health programs—physical health education—distribution of literature on health.
7. County public health nursing program under medical advisory committees of local counties.
8. Mental hygiene program for children.
9. Dental educational and reconstruction program.
10. Postgraduate work for physicians, dentists and nurses.

CRIPPLED CHILDREN

"CORRECT REMEDIAL DEFECTS EARLY"

1. Include in birth certificates the presence or absence of congenital defects.
2. Cooperation of state medical association through advisory committee.
3. Nurses contact physicians, who report cases.
4. Early consultation made available to all.
5. Children treated in approved hospital near home if possible.
6. Schools for crippled children in the larger cities.
7. Reciprocal arrangements between states for transient crippled child.
8. Find and offer aid to the older crippled child.

HIGHWAY ACCIDENTS

1. A study by organized medicine of the causes of death from highway accidents.
2. Assist the law enforcement agencies in reducing the hazards of the careless and drinking driver.
3. Aptitude test on the repeating offenders.
4. Probationary period for young drivers.
5. Cooperate with the American Red Cross in first aid instruction.
6. Filling station attendants to be given instruction in first aid.
7. Develop protection for the doctors and hospitals from irresponsible injured.

OCCUPATIONAL DISEASES

Occupational diseases form approximately 2 per cent of the total disability from industrial causes.

1. Assist employers to cope with employees' health problems with cooperative attitude on the part of the medical profession.
2. Preemployment thorough physical examination.
3. Periodic health examination. (If routine blood tests are made on the employees, treat—don't fire.)
4. Majority of occupational diseases are skin infections, many of which are preventable.
5. Patch testing of employees in occupations producing dermatitis will greatly decrease illness.
6. Teamwork of industrial physician and general practitioner is very desirable.
7. Industrial physician should direct patients with diseases other than those resulting from employment into the channels of ordinary practice.
8. Find the job that best fits the employee physically.
9. Use existing hospital facilities as much as possible.

ANNUAL PHYSICAL EXAMINATION AND HEART DISEASE

1. Educate physicians in better recognition of heart disease.
2. Teach the newer methods of studying functional capacity of the heart.
3. Teach the seriousness of "mild" infections as a background for heart crippling.
4. Teach the role of weight, heredity and environment in the production of hypertension.
5. Educate the physician and layman as to the seriousness of rheumatic infections.
6. Continue to emphasize the role played by syphilis in the problem of heart disease.
7. Train heart cripples of all ages in pursuits that permit them to accommodate their defects.
8. Educate physicians and the public in the importance of periodic examinations.
9. Urge the need for careful periodic examinations after middle life.
10. Stress the need for certain laboratory and x-ray studies at regular intervals: urinalysis, serologic, electrocardiographic and similar laboratory procedures.

CONSERVATION OF EYESIGHT

1. Ophthalmia Neonatorum. Prevent by prompt instillation of silver nitrate, 1 per cent or 2 per cent solution, into the eyes of the newborn.
2. Squint or crossed eyes. Begin treatment not later than age 2.
3. Discourage the use of high explosive fireworks in the hands of children. Reduce fourth of July eye injuries.
4. Examination of school children for visual defects.
5. Avoid eyestrain. A. Correct visual defects. B. Prevent and treat diseases of the eye. C. Install proper lighting. D. Reasonable use of the eyes according to effects of use.
6. Help reduce hazards from industrial accidents.
7. Early detection and treatment of syphilis will reduce blindness.
8. Wipe out trachoma in Indiana.

TUBERCULOSIS

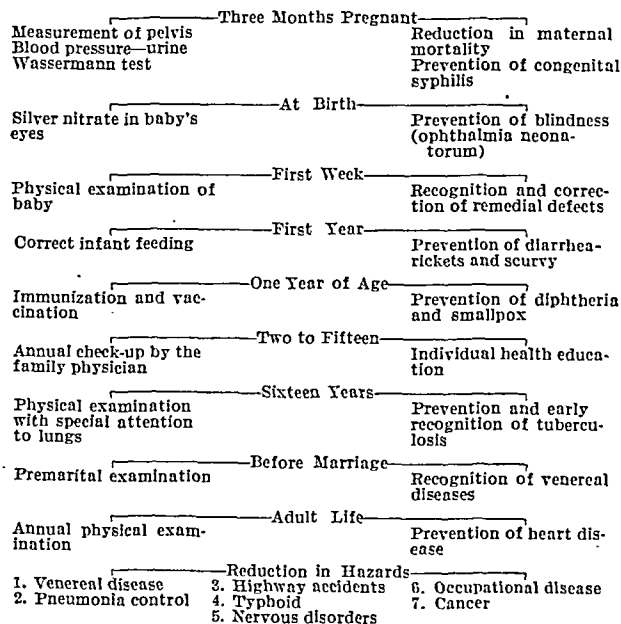

1. Physical examination of every child at age 16, including tuberculin test.
2. Thorough physical examination on entering college or industry.
3. Examination of all nurses on entering training and recheck at regular intervals.
4. X-ray available for positive reactors.
5. Trace contacts and examine.
6. Protect the community from infectious cases by adequate number of hospital beds.

7. Concentration on detection of early cases.
8. Cooperation with antituberculosis association and public health nursing organizations.
9. Continue educational program in high schools.
10. Use collapse therapy when indicated.
11. Rehabilitation program.

SMALLPOX

1. Vaccinate every child at age of 1 year after completion of diphtheria immunization.
 2. Vaccinate again on entering grade school and thereafter at regular intervals by the family doctor.
- Extend the scope of preventive medicine to include other infectious diseases and metabolic disturbances as methods are proved to control them.

Bureau of Publicity
Indiana State Medical Association
1021 Hume-Mansur Building
Indianapolis, Indiana

Resolution Requesting that Editor of The Journal Be Instructed to Confine His Writings to Official Publications of American Medical Association

Dr. Spencer T. Snedecor, New Jersey, presented the following resolution, which was referred to the Reference Committee on Executive Session:

WHEREAS, The Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION is accepted and referred to by the press of the nation as the spokesman of organized medicine; and

WHEREAS, The said Editor conducts a column in the daily press that advises as to health; and

WHEREAS, The said Editor has edited a "Modern Home Medical Adviser," the newspaper advertisement of which claims "money could not buy better health guidance"; and

WHEREAS, The said Editor has admitted he has control over the advertising of this book; therefore be it

Resolved, That the Delegates from New Jersey to the American Medical Association are hereby instructed to introduce a motion into the House of Delegates of the American Medical Association requesting the Board of Trustees of the American Medical Association to instruct said Editor to confine his writings to the official publications of the American Medical Association.

Greetings from Organizations

The Secretary announced that a number of greetings had been received, only two of which were in the form of formal presentation. The Secretary read the two formal messages, the first a telegram from the North American Record Librarians and the second a letter from the president of the Judiciary

Board of the California State Conference of the Bricklayers, Masons and Plasterers of the International Union of America, as follows:

1. North American Record Librarians send heartiest greetings for successful convention. JENNIE C. JONES, President.

2. Trusting your convention and visit to San Francisco and California will be of great benefit to mankind, as well as a satisfaction and pleasure to yourselves. Sincerely, L. C. (HARRY) BLUM.

Attendance at Executive Session

The Speaker announced that when the House reconvenes it will do so in Executive Session and that no one will be admitted except the members of the House and, unless there be objection, the presidents and secretaries of constituent state medical associations and the executive secretaries and employees of the headquarters staff.

On motion of Dr. John Z. Brown Sr., Utah, seconded by Dr. George W. Kosmak, New York, and carried, Dr. Horace Reed, alternate delegate from Oklahoma, was invited to attend the Executive Session.

It was moved by Dr. George W. Kosmak, New York, seconded by Dr. John Z. Brown Sr., Utah, and carried, that when the House recess it do so to meet at 2 p. m.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the representative of the Canadian Medical Association and the representative of the New Zealand Branch of the British Medical Association appear on Thursday, June 16, to present greetings. The motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

The House recessed at 12:15 p. m. to reconvene in Executive Session at 2 p. m.

Executive Session—Tuesday Afternoon, June 14

The House of Delegates was called to order by the Speaker, Dr. N. B. Van Etten.

The Sergeants-at-Arms polled the House, after which the House went into Executive Session at 2:20 p. m.

Action of Committee of the Whole on Resolution Relative to Editor's Writings

Dr. Frederic E. Sondern, New York, asked whether the Reference Committee on Executive Session was ready to report on the resolution introduced from New Jersey relative to the Editor of *THE JOURNAL* and was informed by Dr. J. D. Brook, Chairman of the Reference Committee on Executive Session, that that committee had had no opportunity to consider the resolution nor to grant a hearing to the New Jersey delegation, which had been requested, and could not therefore report at the present time.

Dr. Sondern then moved that the resolution be considered by the House at once because of the importance and urgency of the matter, and that it be considered by the House as a Committee of the Whole. The motion was seconded by Dr. Charles W. Roberts, Georgia, and Dr. Arthur J. Bedell, Section on Ophthalmology, and carried after discussion by Drs. Spencer T. Snedecor, New Jersey; Charles Gordon Heyd, Council on Medical Education and Hospitals, and Morris Fishbein, Editor of *THE JOURNAL*.

Dr. Sondern then moved that this matter be withdrawn from the Reference Committee on Executive Session so that it could be considered by the House, and the motion was seconded by Dr. George W. Kosmak, New York, and carried.

Dr. Sondern further moved that the House of Delegates resolve itself into a Committee of the Whole for greater freedom of debate. Dr. James E. Paullin, Section on Practice of Medicine, seconded the motion and it was carried.

The House of Delegates resolved itself into a Committee of the Whole at 2:28 p. m., with Dr. Frederic E. Sondern, New York, presiding.

The House reconvened in Executive Session at 3:10 p. m., with the Speaker, Dr. N. B. Van Etten, in the Chair.

Dr. Frederic E. Sondern, Chairman, presented the following report:

The Committee of the Whole recommends that the House of Delegates express its complete confidence in and respect for the Editor of *THE JOURNAL OF THE AMERICAN MEDICAL*

ASSOCIATION and bid him godspeed in going forward in the splendid work he is doing.

The Committee of the Whole recommends that the resolution introduced from New Jersey relative to the Editor of *THE JOURNAL* be defeated.

Dr. Sondern moved that the first recommendation of the Committee of the Whole, expressing confidence in and respect for the Editor, be adopted, and the motion was seconded and carried unanimously.

On motion of Dr. Sondern, seconded by Dr. A. T. McCormack, Kentucky, and carried by a rising vote which was unanimous, the House approved the second section of the report of the Committee of the Whole rejecting the resolution introduced from New Jersey.

Special Committee on Publicity

The Speaker appointed the following delegates as a Special Committee on Publicity to censor the publicity emerging from the discussions of the afternoon meeting of the House: Dr. W. H. Seemann, Louisiana, Chairman; Dr. Lewis B. Bates, Isthmian Canal Zone, and Dr. Edgar A. Hines, South Carolina.

Address Prepared by Miss Josephine Roche

Dr. Olin West, Secretary, stated that Miss Josephine Roche, Chairman of the Interdepartmental Committee to Co-ordinate Health and Welfare Activities of the Federal Government, had accepted an invitation forwarded to her on instructions from the Board of Trustees to discuss the work and plans of the committee of which she is chairman, but stated that there was a possibility that she could not attend, and later the following telegram was received:

I deeply regret commitments mentioned in my letter of June 4 make it impossible to be with you to address the House of Delegates on Tuesday, June 14. No other member Interdepartmental Committee available.

The Secretary stated further that he had since received the following message from Miss Roche:

I have talked with the Surgeon General of the United States Public Health Service and he is asking Dr. Warren F. Draper (a member of this House of Delegates) to be ready to read my paper on the work of the Interdepartmental Committee if your Board of Trustees wishes this done. I cannot tell you how disappointed I am not to meet with you and how very much your courtesy is and will continue to be appreciated.

Dr. Warren F. Draper, United States Public Health Service, read the following address submitted by Miss Josephine Roche, which was referred to the Reference Committee on Executive Session, which was asked to retire at once and if possible bring back a report so that it might be considered immediately:

The Interdepartmental Committee was created in August 1935, following the passage of the Social Security Act, in order that the full benefits of the varied federal program under the act's provisions might reach with minimum delay and maximum effectiveness the individual men, women and children for whose aid and service the program was brought into existence. Obviously, duplication of work and effort, conflict in policy or procedure among federal agencies had to be prevented, and common understanding and action developed if the values of the program were to be translated quickly into realities.

As members of this committee, the President designated four assistant secretaries of government departments—the Treasury, Interior, Agriculture and Labor—and the chairman of the Social Security Board.

The committee's first task was the setting up of technical committees to work out immediately cooperative agreements between federal agencies functioning together in the states. Two may be used as illustrations: the agreement between the United States Public Health Service and the Children's Bureau on public health nursing, and the agreement between the United States Public Health Service and the Division of Labor Standards, on industrial hygiene.

The technical committee of Children's Bureau and United States Public Health Service representatives worked out an agreement defining the objectives, setting standards of service, and committing both the Children's Bureau and the Public Health Service to a joint approach to the various state health departments, so that efforts of the two agencies should not be retarded by any duplication of effort or multiplicity of super-

vising units, with the inevitable misunderstandings and confusion in the field which would result.

The industrial hygiene agreement was the result of a desire on the part of the Department of Labor and the Public Health Service to promote in the states the establishment of industrial hygiene units in the state health departments which would cooperate with the state labor agencies in the pursuance of the common objective—protection of the working population from industrial health hazards.

Other technical committees working out similar interdepartmental agreements for administrative coordination are those on crippled children and the needy blind.

While there has not been, of course, 100 per cent success in eliminating duplication of effort and competition between interested agencies in the states, we are convinced that the three years experience has evolved a useful and unique mechanism for coordinated procedure: useful in that technical groups may meet together and, through conference and interchange of experience, approach mutual understanding and agreement based on a solid foundation of fact; unique in its simple combination of facilities to provide direct administrative action when technical groups have determined the procedures through which harmony of action may be achieved.

Working under the instruction of the executive order "to study and make recommendations concerning specific aspects of the health and welfare activities of the government" are the technical committees on recreation, nutrition, crime prevention and parole, and medical care.

In the work of the last-named committee you have, of course, a special interest, and our interdepartmental committee is deeply grateful and encouraged to know that a number of you, including some of the officers of the American Medical Association, are to be with us at our national health conference July 18, 19 and 20, when the full report of this technical committee will be submitted and discussed.

At the time the Technical Committee on Medical Care was formed the national health survey of the Public Health Service was nearing completion. You are familiar with the results of that survey, covering, as it did, some 800,000 families, including 2,800,000 persons, and supplemented by reports from physicians, health officers, and institutions providing medical services. This survey made it possible to measure health needs quantitatively and to determine the degree of correlation among all the factors involved. It provided an index not only to the prevalence of disabling illness for the population as a whole but according to age, sex, occupation, family income, living standard and size of community. It made it possible to weigh these factors in relation to mortality figures as well as to medical and nursing care received and to the availability of hospital facilities.

The overwhelming central fact established by the national health survey is this: that with poverty goes not only a higher rate of sickness but a deficiency of medical care. These correlations were proved not only for the relief group but for struggling families above the level of relief. Many may have considered these facts too obvious to require proof, and certainly they had been supported by innumerable smaller studies. But never before had such a mountain of evidence been assembled to sustain the conclusion that among the poor there is an excess of sickness and death which requires preventive services and medical care proportionately greater than are required in the higher income groups. And never before had it been so convincingly shown that in many areas and localities those economic groups which are most in need of preventive services and medical care are receiving far less of both than are families with larger individual financial resources.

The national health survey irresistibly drew the attention of the interdepartmental committee to the national problems of health and medical care. The Technical Committee on Medical Care was directed to study the results of the national health survey and to correlate with them all other available data on the subject. After more than a year of work the Technical Committee produced a report on "The Need for a National Health Program," which was transmitted to the President last February. Already a part of this report, in which the health needs of the country are stated comprehensively, yet concisely, has been made public; with facts and conditions such as it sets

forth you have long been familiar, through the years of generously contributing your skill and services to the destitute and broken men, women and children who have turned to you for aid in illness and suffering. It is to be hoped we may have graphically given to us by your own survey the full extent of the free services of the medical profession. It would be a good thing for every citizen to realize more clearly the immensity of the philanthropic burden which the members of the medical profession voluntarily assume.

We have the information as to health and medical needs in broad national terms. Your survey should be of great value in amplifying existing data regarding many specific localities and in presenting needs as they are seen in the field by practicing physicians. In this, as in all other fields, it is necessary always to keep in mind the difference between active demand and actual need. Our present picture of the total need may be amplified or modified in detail as further special studies are made. But the report of the Technical Committee on Medical Care, based on all available data—including direct contacts with large numbers of individual citizens as well as with professional groups and agencies—establishes conclusively the existence of grave and far-reaching needs.

Together with you, those of us who have been battling on the economic front against unemployment, starvation wages, indecent housing and utterly inadequate food find nothing new, but only shocking confirmation of the extent to which human and economic waste has been permitted to go on, when we read from the Technical Committee's report on The Need for a National Health Program such facts as the following: On an average day of the year, there are four million or more persons disabled by illness. Every year seventy million sick persons lose over one billion days from work or customary activities. In 1936, nearly a quarter of a million women did not have the advantage of a physician's care at delivery; 15,000 of these were delivered by neighbors or relatives; 223,000 were delivered by midwives, most of whom are untrained and ignorant.

In 1937, of forty-nine state health officers responding to a questionnaire, only two reported the facilities for maternal care in their states as adequate. In large areas and groups of the population the death rates between the second and the twelfth month of infancy are as high as they were for the whole country twenty years ago. Community measures for the control of communicable disease, so necessary in checking the acute infectious diseases of childhood, are inadequate in the greater proportion of rural counties throughout the country.

Each year, 40,000 young adults between the ages of 15 and 45 die from the ravages of tuberculosis. The deaths among these young adults represent about three fifths of all deaths from this cause.

Preliminary results from the national health survey indicate that disabling illness in the relief population occurred in 1935 at an annual rate 47 per cent higher for acute illness and 87 per cent higher for chronic illness than the corresponding rates for families with incomes of \$3,000 and over. The annual days of disability per capita in the relief group were found to be three times as great as among upper income families; the nonrelief population with an income under \$1,000 showed a rate of disability over twice that of the highest income group. One in every twenty family heads in the relief population was unable to work because of chronic disability, as contrasted with only one in 250 heads of families with incomes of \$3,000 and over. Children of relief families experienced 30 per cent greater loss of time from school and usual activities because of illness than did children in families in moderate and comfortable circumstances. Only 70 per cent of the cases of disabling illness among relief persons received medical attendance exclusive of hospital care, compared with a figure of 83 per cent for those with a family income of \$3,000 and over. The average medical services per case of disabling illness were about 50 per cent higher in the highest income group than among persons on relief. Bedside nursing care in the home was given to less than 1 per cent of the disabling illnesses among persons on relief; the proportion so attended in the group with family income of \$3,000 and over was 10 per cent.

These are only a few examples—plucked more or less at random—from the data which we have about the low income

groups of our people. We must keep constantly in mind the fact that approximately fifty million of our population are in families with an annual income of less than \$1,000 a year.

When facts of denial and destruction of human values, such as these I have mentioned, are discussed in terms of the size of the population involved—the tens of millions of men, women and children who are their victims—the problem of providing adequate health and medical services obviously demands concerted public action for its satisfactory solution.

In calling the National Health Conference, the Interdepartmental Committee is carrying out the suggestion of the President that it invite representatives of the interested public and of the medical and other professions to examine the health problems in all their major aspects and to discuss ways and means of dealing with these problems.

The National Health Conference is planned as a working conference. To provide the best opportunity for frank discussion, it is necessary to limit the number of participants, but the Interdepartmental Committee hopes that they will be truly representative of both the professional groups, who have the technical knowledge, and of the general public, which is vitally interested in the distribution and application of this knowledge.

It is hoped that the conference will contribute to two ends: First, a better understanding of national needs in the field of health and medical care. Second, the formulation of policies which will enable the medical and other professions, private organizations, federal, state and local agencies, and individual citizens, to cooperate in efforts to meet these needs.

The Technical Committee on Medical Care will submit to this conference not only its analysis of needs but certain tentative recommendations as to means of meeting them. These recommendations have been submitted to the President, and it is at his suggestion that they will be submitted to the consideration of the National Health Conference. The report deals with several broad problems: First, the need for more comprehensive public health services to combat specific diseases or groups of diseases, such as tuberculosis, the venereal diseases, pneumonia, malaria, cancer and other chronic diseases of middle and old age, mental disease and deficiency, and industrial hazards.

Secondly, the need for expansion of maternal and child health services; the Technical Committee estimates that half the infant deaths and half the maternal deaths could be prevented by the application of the knowledge and skill which your profession now has.

Thirdly, the shortage or unequal geographic distribution of hospitals, clinics, doctors, dentists, nurses and other agencies and trained experts in the field of health and medical care.

Fourthly, means of providing more adequate medical care for recipients of public assistance and other persons of very low income.

Finally, methods of financing the sickness costs of self-supporting persons of limited means.

We do not intend to ask the National Health Conference to take formal action on any part of this report. We hope that none of the groups or individuals participating in the conference will attempt to make premature judgments or urge others to do so. Our purpose is to obtain the frankest discussion of ways and means of dealing with these immense and complex problems. We hope that the participants in the conference and, subsequently, other groups and individuals throughout the country, will give us the full benefit of their knowledge, experiences and ideas.

No one formula or program can possibly be found adequate to meet the varied needs, but a composite of many efforts and plans, some already tested, some in experimental stages, some not yet under way, can and must be found. We believe that, by providing an opportunity for an interchange of views between representatives of the medical and other professions, of various agencies and of the general public, the National Health Conference will dissipate misunderstandings and work toward a meeting of minds on the beginning of a coordinated national health program.

That there will be concerted public action eventually for such a program no one measuring the human needs and denials

can doubt. In this great democracy with its unsurpassed resources and potentialities for human progress, one third of our people are not going indefinitely to remain ill fed, ill housed, ill cared for in sickness. Already they are on the march, and the only question which remains is whether highly specialized groups, experienced and trained in ways and means of meeting human needs, are going courageously and quickly to offer all they can give in constructive and progressive leadership and help in the meeting of the vast human problems of today.

You have your instruments of precision for diagnosis and treatment; your technics for prevention and cure are among the wonders of the modern world. How can we help to bring them to all our people who need them? That is the question which we submit to you today, the question we shall ask at our conference, must go on asking until we find the answer.

Report of Advisory Committee on Supply of Medical Care

Dr. W. F. Braasch, Chairman, presented the following report of the Advisory Committee on Supply of Medical Care, which was adopted on motion of Dr. Braasch, seconded by Dr. George W. Kosmak, New York, and carried:

Widely publicized statements have been made by so-called leaders of medical science, social reformers and welfare politicians to the effect that the need for medical reform was urgent and that immediate radical changes were essential in order to give adequate medical care to countless hundreds who were now being neglected. Estimates of widespread inadequacy of medical care, rated as high as 50 per cent in the indigent groups, made some of us gasp. These claims have gone practically unchallenged except by the organized profession and are still being widely quoted and accepted by press and public. Information concerning the distribution of medical service which has been quietly accumulated in recent years at the headquarters of the American Medical Association was quite contrary to statements emanating from sociologic and welfare groups and from surveys inspired by governmental agencies. The desirability of more accurate data became very evident and, when voiced by the American Public Health Association, the trustees and officers of the American Medical Association lost no time in starting a nationwide survey of the actual supply of medical care. In contrast to previous health surveys made by laymen untrained and ignorant of the intricacies involved, this survey was to be made by the doctor himself.

After thorough preliminary study by the Bureau of Medical Economics and the officers of the Association, it was decided to use the county medical society as the basic unit of the survey. It was not a case of "passing the buck" as was claimed, but it is the only way in which the medical conditions existing in different sections of the country could be determined. It was also decided to include every phase of activity related to medical service, so as to make the survey as complete as possible. For this purpose forms were compiled which, when filled out, should give an exhaustive survey of the entire medical field. Authoritative data concerning the need and supply of medical care will at last be available and we shall now be able to discuss intelligently any inadequacy which may exist.

It is evident that this survey will furnish us not only a great variety of valuable data related to medical care but many by-products of importance as well. We should be able to determine, for example, the following data concerning any deficiency in supply of medical service: its geographic distribution; the type of community, and the social status of the patient involved. We should also discover why these conditions exist, whether public officials or institutions are derelict, and in what respect. It would be most disappointing if from the great mass of data accumulated no suggestions developed to improve the present distribution of medical service. Not the least important will be the effect of the survey on public opinion and incidentally the sympathetic reaction on the part of laymen who have participated in the accumulation of data. Finally, and possibly of greatest importance, this survey should draw the component parts of our Association into closer relationship with activities centered in the Association headquarters.

Every effort has been made by the officers of your Association to publicize and arouse interest in the survey by means of articles in the Organization Section of *THE JOURNAL*, printed information sent to state organizations for distribution, and by individual efforts of the officers and members of the Board of Trustees. Dr. R. G. Leland, Director of the Bureau of Medical Economics, has responded to the requests of numerous state and county societies and in recent months has devoted much time and energy to giving personal aid to its expedition.

An advisory committee was appointed by the Board of Trustees, composed of men from various parts of the country who have been interested in economic affairs. At our initial meeting many of the problems involved were discussed. The members of the committee were unanimous in recognizing the importance of the survey and urged that it be carried out as thoroughly as possible. As might be expected, opinions as to the method of conducting the survey in the various parts of the country were quite different. It was felt that instructions in conducting the survey and in filling out the different forms should not be too didactic. It seemed desirable to let the various sections of the country devise their own methods of procedure. Each member of the Advisory Committee agreed to take an active part in the survey of his own state and also, so far as possible, to lend his efforts in an advisory capacity to the activities in the adjacent states. It was felt that this great attempt to make an inventory of national medical supply should by no means be final and that in some of its phases these efforts should be continuous.

What progress has been made so far? Although the survey has been carried on with enthusiasm in some states, we regret to say that the response in some parts of the country has been lukewarm and in several states very disappointing. There are scattered reports of open hostility and back-sniping on the part of individual members, insinuations that the survey will be worthless and will lay us open to criticism. The latter can happen only if we do not take the survey seriously and cooperate in every way possible.

It has been observed that those states were most successful which had first established a good, working, preliminary organization. The exact form of the organization varied in the different states. In most cases the activities were centralized in the office of the secretary of the state association. In several states general supervision was left to the committee on medical economics, and detailed supervision in the various counties or districts of the state was subdivided among the members of the council or the board of trustees representing these districts. In most counties the details of the survey were in charge of a special committee appointed for this purpose. Contact was made with the county secretaries either by means of bulletins, notices in state medical journals, or personal visits from members of the economics committee, the council or the state secretary. The survey went over best in counties in which a preliminary informatory gathering had preceded distribution of the blanks. Meetings were held in the larger communities of the county, in which a representative group was given personal instruction by officials of the state organization or by the county secretary. In some states statewide and district meetings of county representatives were held and at the gatherings state and national officers, including Dr. Leland himself, gave individual advice. Field work to facilitate the survey throughout the state was carried on by the secretary or other officer of the state association in some areas. In others it was done in conjunction with the chairmen and members of the economics committee or of the council. In one state a group of senior medical students was employed to facilitate the survey.

In order to demonstrate the different methods of organization and the means employed in various states, we suggested that the Bureau of Medical Economics prepare an exhibit in the American Medical Association section of exhibits. We trust that many officers of county and state societies, as well as members of the Association, will avail themselves of this opportunity to profit from experience already had. In addition, the members of the Advisory Committee will be available during the meeting in order to discuss problems in the conduct of the survey which may have appeared in any state or county organization.

The cost of conducting the survey varies widely in different localities. It has been found necessary to devote comparatively little money to it in most of the state associations, averaging only a few hundred dollars. The cost of the survey in the larger communities has been borne by the local county societies, with the assistance of the state medical societies in some instances, and has caused no excessive burden. The expense involved in accumulating and evaluating the various data assembled in the Association headquarters will not be excessive and has already been taken care of by the Board of Trustees. The total expenditure entailed should not be a serious problem and promises to be insignificant in comparison with the value received.

With regard to the various forms, as might be expected, form 1, which deals directly with the physician himself, is criticized most. Confusion arose in the minds of some as to how to answer questions 1, 2 and 3 of this form. Since many physicians did not keep a close record of indigent patients, it was difficult to give an exact answer to these questions. However, it was held by Dr. Leland and others that an approximate estimate of the number of patients treated would suffice. In some places physicians are keeping records for a month or more to get dependable estimates.

It is generally recognized that no large survey can be 100 per cent accurate. Even life insurance companies are unable to make an exact survey. The most we can expect to get will be a pattern or sampling of the medical situation in each county and state. Although it is important that the sampling should be as accurate as possible, it is of equal importance that every physician should do the best he can in filling out the blanks.

In order to increase the accuracy of data from several questions in form 1, it was thought advisable to make a separate spot survey over short periods of time. Accordingly, the Bureau of Economics is sending out record forms to cover these different periods, in July, October and January. These blanks, form 1F, will permit the keeping of an accurate record of patients during those periods.

The importance of answering questions 7 and 9 in form 1 cannot be overemphasized. In fact, the actual value of form 1 would be comparatively little unless these questions were fully considered. We are particularly interested in knowing what the physician's reaction is toward the problems of medical care and what remedies he can suggest for their improvement under the present circumstances.

In large and highly industrialized communities, considerable difficulty arose in filling out form 8. In order to facilitate and simplify the gathering of information, special blanks were prepared by the survey committee in Pennsylvania and in other states. The Bureau of Medical Economics has repeatedly advised the use of additional questions or forms when necessary to acquire a complete understanding of the problem of medical demand and supply. We understand that the blanks sent out to the various institutions and social agencies have been filled out much more promptly and completely than those sent to the physicians themselves. It would be most unfortunate for the success of the survey if this discrepancy should continue.

It cannot be made too emphatic that this is primarily a survey of the practitioners of this country. We are interested in finding out the direct results of their observations and their conclusions as to the supply of medical service. We are not interested so much in the theoretic reforms of many of the so-called leaders of medicine, which in most cases are products of the noble thought and the library table. It is not of great importance to find out what those who are engaged in teaching or cloistered specialists and institutional doctors think about medical care, and we already know what governmental officials and social workers think. The facts of the situation must come from those who are in direct contact with the actual practice of medicine. We must find out from them to what extent reform in medical care is needed and get their opinions as to how it can best be accomplished.

If there ever can be a mandate from the American Medical Association to its members, this survey should be so considered. Now that we are definitely committed to the survey, it is up to us to make good; if we do not, the situation will be most disastrous.

The best advice the advisory committee can give is that each member of the House of Delegates shall individually take on himself the responsibility of the success of the survey in the district that he represents. If you find that the survey is lagging in your district, get after the officers of the backward state or county society and convince them of the great importance of its completion. See to it that effective organization is established at once. Ask the member of the advisory committee or the Board of Trustees in your part of the country, ask Dr. Leland and the officers of the American Medical Association, for their active cooperation, and it will be forthcoming. How many of the members of this House have filled out form 1? If you have not, you should do so immediately. Every one of you should see to it that your county society sends in a return as complete and as quickly as possible.

Gentlemen, this is your survey, not that of any bureau, committee or officer of the Association. It is squarely up to you and your constituents to carry it through successfully. It is no exaggeration to state that this survey may have a profound influence on the future course of American medicine.

Report of Reference Committee on Sections and Section Work

Dr. Robert A. Peers, Chairman, presented the following report, which was adopted on motion of Dr. Peers, seconded by Dr. John Z. Brown Sr., Utah, and carried:

Your Reference Committee on Sections and Section Work has reviewed the program and heartily commends the many practical, authoritative and up-to-date presentations, which cover a wide variety of subjects. It comments especially on the inclusion of some of the diseases peculiar to the Orient, which are of increasing importance because of the rapid methods of travel. This transmission of disease is a medical problem which the members of the Council on Scientific Assembly and the section officers anticipated and, by their foresight, made the members of the Association conscious of these new dangers.

The subjects presented, covering as they do new drugs, recent operations, modern therapeutic measures, glandular therapy, allergic reactions, blood dyscrasias and the excellent symposiums on cancer, syphilis and radiology, emphasize many of the advances made in the past year in clinical medicine.

The report of the Council on Scientific Assembly has been reviewed and your reference committee particularly commends the suggestion of the Council that scientific sections of the Association may combine their sessions when the subjects presented are of mutual interest. To further the attendance at the general scientific meetings and sectional programs, your reference committee would be happy to endorse any activity of the Council on Scientific Assembly that would discourage independent societies from holding their meetings during the sessions of the American Medical Association.

The scientific exhibits maintain the high standards set in previous years and continue to offer to the alert physician the finest and most comprehensive postgraduate instruction obtainable. The individual exhibits are worthy of praise and the subsidized research projects, such as those on fractures and anesthesia, continue to attract a great number of our members. Your committee recommends that these subsidized exhibits of fractures seek the cooperation of other sectional interests. The experimental problems in medicine and surgery as presented in the Scientific Exhibit should have special commendation.

Your reference committee records its appreciation of the work done by this very active Council on Scientific Assembly, the section officers and those officially concerned with the Scientific Exhibit.

Respectfully submitted.

ROBERT A. PEERS,
Chairman.
ARTHUR J. BEDELL.
BURT R. SHURLY.
E. H. SKINNER.
TOM B. THROCKMORTON.

Report of Reference Committee on Medical Education

Dr. William D. Johnson, Chairman, presented the following report, which was adopted on motion of Dr. Johnson, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried after discussion:

Your reference committee, having studied the Resolution Approving in Principle the Indiana Plan of Health Education and Preventive Medicine, offered by Dr. H. G. Hamer at the morning session, commends the resolution and moves its adoption.

Respectfully submitted.

WILLIAM D. JOHNSON, Chairman.

Report of Reference Committee on Executive Session

Dr. J. D. Brook, Chairman, presented the following amended report of the Reference Committee on Executive Session and stated that credit for the preparation of that part of the report referring to the address prepared by Miss Roche was due Dr. W. F. Braasch, Minnesota:

1. The resolution concerning the movie film entitled "The Birth of a Baby" presented by Charles W. Roberts, Georgia, suggests three points: (a) its educational value; (b) age limit for showing, and (c) the policy of the House of Delegates on the showing of the film.

To the first question your committee replies by saying that it believes that the film has a definite educational value and that maternal and child welfare endeavors would be enhanced by its release.

To the second question your committee replies by recommending that, as children would obviously fail to comprehend the import of the film, its showing be limited to adults.

In reply to the third question concerning the policy of this House, your committee submits the following: Because the original contract with the producers was such that the film should not be shown except by consent of the county medical society and because of our inalienable belief in "states' rights," your committee labels the question of showing the film a problem of the various state societies and their component county organizations and recommends that it be so handled.

2. Contraception and Venereal Disease Prophylactics: In the report of the Board of Trustees on page 97 of the Handbook appears a statement of fact regarding the passage of laws by four states controlling to some degree the sale or distribution of appliances, drugs and medicinal preparations intended or having special utility for the prevention of conception and venereal diseases. We believe the enactment of these laws is a step in the right direction, as it limits the sale and distribution of contraceptive materials to responsible persons; namely, the physician and the pharmacist.

On pages 142 and 143 of the Handbook is found the Report of the Committee to Study Contraceptive Practices and Related Problems as presented to the Board of Trustees. The committee asks the acceptance of the following statement by the House of Delegates:

It is not the function of the American Medical Association to tell physicians what therapeutic advice they shall offer patients. However, it has been its policy to investigate various procedures, devices and drugs, and to publish the results of such studies in its official publications for the information of the profession.

The instructions to the Council on Pharmacy and Chemistry and the Council on Physical Therapy to investigate further the materials, devices and procedures used for the purpose of contraception do not indicate any change in the usual policy of the Association, nor do they constitute an endorsement by the Association of contraceptive practices.

While there are still some phases of the subject which have not been clarified, particularly as to methods and devices used for contraceptives, your committee endorses the committee's statement and desires to reiterate the stand taken by this house in 1937 that the problem is essentially a medical proposition.

•3. Address prepared by Miss Josephine Roche: Your committee believes that it expresses the sentiment of the House of Delegates in saying that it is glad to have received a communication from the chairman of the Interdepartmental Committee, Miss Josephine Roche. It is particularly welcome since it is the first official communication that the American Medical

Association has received from this important governmental committee.

Your committee notes with interest that the studies have resulted in the coordination of health activities involved in the Public Health Service, in the Department of Labor and in the Children's Bureau. It trusts that future results will bear out the promise of increased efficiency.

Possibly the most interesting data quoted are those which would indicate a much higher rate of sickness in the subeconomic groups. This raises the question whether the economic factor involved is not of greater importance than is the lack of medical care in the cause of illness.

The address contains many interesting statements regarding medical care, some of which are at variance with data accumulated in the files of the Bureau of Medical Economics.

Although your committee agrees in principle with many of the objectives which the Interdepartmental Committee has in view, nevertheless there may be some danger involved in their execution. Your committee has in mind, for example, the devotion of huge sums of money to the care of certain specified diseases. Experience has already shown that such action may produce a lack of balance in the entire program for medical care which can retard rather than expedite progress.

Your committee emphatically agrees with the statement in the address which reads as follows: "No one formula or program can possibly be found adequate to meet the varied needs of medical care."

Your committee notes with satisfaction that a group of physicians has been invited to take part in the discussions of the forthcoming national health conference and that it includes officers and leaders of the American Medical Association. This will make available a vast amount of information concerning the subjects involved which has been accumulated by the American Medical Association over a period of years, including the results of our national survey of medical service. Your committee is confident that the official representatives will be guided by the principles and opinions which have been repeatedly expressed by the House of Delegates.

Respectfully submitted.

J. D. BROOK, Chairman.
W. F. BRAASCH.
WILLIAM R. BROOKSHER.
DON F. CAMERON.
MEREDITH MALLORY.

On motions of Dr. Brook, duly seconded and carried after discussion, the report of the Reference Committee on Executive Session was adopted as amended section by section and as a whole.

Report of Board of Trustees

Dr. Arthur W. Booth, Chairman, Board of Trustees, stated that the Deputy Commissioner of Internal Revenue had recently reversed the decision of a previous commissioner and held that the American Medical Association is not a scientific or educational corporation within the meaning of section 101 of the Revenue Act of 1936 and corresponding sections of prior revenue acts, but rather a business league and, therefore, not exempt from tax under the Social Security Act.

On receipt of that decision the Board of Trustees instructed the Secretary and General Manager to collect a tax from the employees, to make payments and, in the meantime, to take the matter up with a competent tax counsel. This was done and an opinion has been secured from the tax counsel. The Board yesterday voted to ask the Bureau of Internal Revenue for reconsideration. The recent decision of the Commissioner of Internal Revenue will involve large expenditures for the current year. No opportunity has been given the Association to provide the money for this tax. The Board is therefore in the position of having to find \$55,000 and possibly \$100,000 for the current year alone.

The Speaker announced that this report was read for the information of the House.

Dr. Austin A. Hayden, Secretary, Board of Trustees, made an announcement concerning the Opening General Meeting, after which the Speaker declared that the House would recess until 1 p. m. Thursday, June 16.

The House recessed at 4:30 p. m. to reconvene on Thursday, June 16, at 1 p. m.

Third Meeting—Thursday Afternoon, June 16

The House of Delegates was called to order at 1:15 p. m. by the Speaker, Dr. N. B. Van Etten.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, reported that there was a total registration of 170, which was only four below the possible number that could be registered.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of the Minutes

It was moved by Dr. Arthur C. Morgan, Pennsylvania, seconded by Dr. H. B. Everett, Tennessee, and carried, that the House dispense with the reading of the minutes.

Address of Dr. Carl H. Vrooman

The Speaker presented Dr. Carl H. Vrooman, Vancouver, B. C., Canada, delegate from the Canadian Medical Association, who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates of the American Medical Association:

In presenting the greetings of the Canadian Medical Association to the members of the American Medical Association I wish to express the great pleasure it gives a Canadian to be present at these meetings or to welcome members of the American Medical Association at our own meetings.

I have been particularly impressed in listening to your proceedings by the similarity of our problems and the democratic methods used in solving them. Socialization of medicine looms large in your discussions and has the same lively interest with us, particularly so in my own province of British Columbia, as some of you may know. You have no monopoly on diversity of opinion in the maze of plans, legislative and otherwise, that are proposed for the care of the sick. It is a pleasure to hear your leaders emphasize that the care of the sick is the business of the physician. Ours are not the mild concerns of life, but we are entrusted by the people with their most valuable asset; namely, health. Sometimes I think we doubt that this trust imposed on us as individuals is transferred to the democratic organizations representing us whose duty it is to solve these medicosocial problems.

Our experience in Canada and particularly in British Columbia has been that the people trust organizations such as yours, or organized medicine, more than we sometimes think, and that the ill considered and amateurish solutions so often loudly presented do not carry the weight they seem to with the general public. People in your country and mine still trust democratic government and as long as your association and ours continue to be the democratic forum of the medical profession that trust will continue.

I have to read the official letter of Dr. Routley conveying the official greetings. This is to the President, Officers and Members of the American Medical Association.

Dr. Vrooman read the following letter of greetings from the Canadian Medical Association:

The Canadian Medical Association desires to take this opportunity of presenting, through its official fraternal delegate, Dr. C. H. Vrooman of Vancouver, most cordial good wishes for the success of the annual meeting of the American Medical Association being held in the city of San Francisco.

The Canadian Medical Association is deeply sensible of the spirit of good will which prevails in each association toward the other. You have always extended the hand of fellowship to members of the Canadian Medical Association who have been privileged to attend your meetings. We, in turn, would like to think that Fellows of the American Medical Association are conscious of the fact that they are always welcome guests on Canadian soil and at meetings of the Canadian Medical Association.

On behalf of the President, Officers and Members of the Canadian Medical Association, I beg to remain,

Fraternally yours,

T. C. ROUTLEY, M.D.,
General Secretary.

Report of Judicial Council

Dr. George Edward Follansbee, Chairman, presented the following report of the Judicial Council acting as a reference committee, which was adopted on motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. G. Henry Mundt, Illinois, and carried:

Your committee has in several meetings given prolonged consideration to the Resolution on Teaching in Schools of Chiropody introduced by Dr. G. Henry Mundt, Illinois. The sponsor of the resolution and several of the delegates have appeared before the committee; arguments both pro and con have been heard. The more the matter has been studied, the more complicated it becomes. The committee, being the Judicial Council, is unwilling to make recommendation to this House unless it feels assured that its recommendation is correct and sound. Further information and further investigation, more than can be accomplished in the limited time available at this session of the House, is needed. The resolution does not pertain to an acute situation.

For these reasons your committee recommends that the resolution be laid on the table, with the expectation that, if a like resolution is presented at the next annual session of the House, the Judicial Council will be prepared to give recommendation based on adequate knowledge and sound judgment, if so requested and if a similar resolution is introduced.

GEORGE EDWARD FOLLANSBEE, Chairman.
JOHN H. O'SHEA.
WALTER F. DONALDSON.
JOHN W. BURNS.
E. R. CUNIFFE.

Resolution on Visual Standards for Operating Motor Vehicles, from the Section on Ophthalmology

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, which was adopted on motion of Dr. Bedell, seconded by Dr. Charles H. Goodrich, New York, and carried after discussion:

WHEREAS, For many years state licensing boards have asked for official visual standards for operating motor vehicles; and

WHEREAS, A committee of the Section on Ophthalmology of the American Medical Association has had this problem under serious consideration for many years and has made its report; and

WHEREAS, This report was accepted by the Section on Ophthalmology of this Association; and

WHEREAS, The delegate of the section was directed to present this report to the House of Delegates; be it

Resolved, That the following be accepted as the approved American Medical Association standards:

A. For an Unlimited License:

1. Visual acuity with or without glasses of 20/40 Sn. in one eye and 20/100 Sn. in the other.
2. A form field of not less than 45 degrees in all meridians from the point of fixation.
3. The presence of binocular single vision.
4. Ability to distinguish red, green and yellow.
5. Night blindness not to be present.
6. Glasses when required be worn while driving and those employed in public transportation be provided with an extra pair.

B. Visual Standards for Limited License:

1. Visual acuity of not less than 20/65 Sn. in the better eye.
2. Field vision of not less than 60 degrees horizontally and 50 degrees vertically from point of fixation in one eye.
3. Diplopia not to be present.
4. Glasses to be worn when prescribed.
5. Coordination of eye, mind and muscle to be fully adequate to meet the practical visual road tests.
6. A limited license not to be issued to those employed in public transportation.

C. Renewals, Retesting and Reexaminations:

1. Renewals of license to be issued at least every third year. The applicant shall with each renewal make a declaration that he knows of no visual defect which has developed during the past year.
2. Retesting of acuity to be made at least every six years.
3. If any visual defects have developed, an examination by an ophthalmologist and the report thereof, to be required before reissuing the license.
4. License to state thereon the specific limitation for driving.

Resolutions from the Section on Nervous and Mental Diseases Recommending Alteration of Existing Laws Relative to Contraceptive Information

Dr. Tom B. Throckmorton, Section on Nervous and Mental Diseases, presented the following resolutions, presented to the Section on Nervous and Mental Diseases by Dr. Foster Kennedy, New York, which were referred to the Board of Trustees on motion of Dr. Throckmorton, seconded by Dr. Arthur C. Morgan, Pennsylvania, and carried:

WHEREAS, State and federal legislation governing the control of reproduction is conflicting and renders certain phases of medical practice illegal, it is important that the profession of medicine as a whole should clarify and lead in these questions involving medical practice and procedures. The importance of such control in medical practice where such control constitutes a therapeutic measure is obvious to enlightened lay opinion throughout the civilized world and should be obvious to all medical men not mediocally minded; therefore be it

Resolved, That we hereby recommend the alteration of existing laws wherever necessary, so that physicians may legally give contraceptive information to their patients; and be it further

Resolved, That we recommend an amendment to sections 211, 245, 311 and 312 of the Federal Penal Code as follows: "Standard medical and scientific journals and reprints therefrom and standard medical works which contain information regarding the prevention of conception are not nonmailable under this section"; and be it further

Resolved, That a full and frank discussion be given in regard to these subjects by the proper deliberative council of the American Medical Association.

Report of Reference Committee on Legislation and Public Relations

Dr. Terry M. Townsend, Chairman, presented the following report:

Report of Bureau of Legal Medicine and Legislation and Resolution on Recognition of Acting Assistant Surgeons of the Spanish-American War: A survey of the report of the Bureau of Legal Medicine and Legislation discloses the vast amount of work done. It recites legislation proposed by gentlemen who are not fully familiar with the economics of medicine and their effect on the public. It narrates the large subsidies proposed for federal health activities in the prevention and treatment of cancer, venereal diseases, tuberculosis, infantile paralysis, blindness, deafness, silicosis, medical care for transients, and hospitals for the medically needy. Much of this legislation died in committee or failed to pass.

During the Spanish-American War many physicians volunteered their services in the capacity of Contract or Acting Assistant Surgeons. They rendered the same service, tolerated the same living conditions and took the same risks as commissioned medical officers, but they could not be given commissions as the then existing laws made no provision for such commissions. It is only the lack of these commissions that now stands between these physicians and their old age service pensions. Nurses who served in the same status in the same war have long since received their pensions. The same thought is embodied in the resolutions introduced by Dr. Elbridge J. Best, California. Your reference committee endorses these resolutions and recommends that this House of Delegates commit itself to continue support of legislation to provide pensions for Contract and Acting Assistant Surgeons who served in the Spanish-American War, the Philippine Insurrection and the Boxer Uprising.

Among the several bills introduced in Congress proposing reorganization of the executive branch of the federal government, all propose the establishment of a Department of Welfare and none suggest the creation of a Department of Health. Since the health of the people is of such importance to the government, your committee recommends that this House of Delegates reiterate its demand for a federal executive department to be designated as the Department of Health, with a Doctor of Medicine at its head who shall have general supervision and direction of the affairs of the federal government pertaining to the health of the people.

Workmen's compensation legislation is expanding its scope to provide compensation for disability resulting from any occupational disease arising out of and in the course of employ-

ment. To safeguard the injured workman, the carrier and the physician, there should be medical membership on each compensation commission or industrial board. Only competent doctors of medicine can evaluate and determine the worth of medical evidence, which constitutes the crux of each decision on each claim presented to the commission or board. Your committee recommends that the constituent state medical associations be advised to take such action as may be necessary to procure medical memberships on compensation commissions and industrial boards.

Your committee congratulates and compliments the Medical Society of the District of Columbia on its successful efforts in preventing prohibitive legislation on animal experimentation.

Report of Bureau of Medical Economics: That portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics deserves your commendation. Especially does your committee recommend your commendation of the statements pertaining to the study of medical care, group hospitalization and the expansion of hospital functions into the field of medical practice. The developments in these fields are, in the opinion of your committee, clearly and fairly set forth. Your committee recommends that the Association's activities in these fields be in the same careful manner that has characterized its work up to the present time.

Your reference committee has studied carefully the objectives of the study of medical care called for in the resolutions passed by the Board of Trustees in December 1937. This project is but a furtherance and extension of the encouragement which the American Medical Association has previously given to state and county medical societies to develop means by which all persons might readily obtain medical care at fees commensurate with their ability to pay; it is consistent with the repeatedly expressed position of this Association that the medical and preventive medical services and facilities can be supplied satisfactorily and efficiently only when the needs are known and then the procedures for supplying these needs must vary according to local conditions.

Your committee is unanimously of the opinion that state and county medical societies cannot afford not to develop for their respective jurisdictions the most accurate and complete information that will enable them, with the assistance of the correlated professions and other agencies concerned with medical and preventive medical services and facilities, to maintain continuously medical care that is sufficient in amount and satisfactory in quality.

Since it is contemplated in the resolutions passed by the Board of Trustees that some state and county medical societies may find it necessary to develop preferable procedures for supplying the needs where medical services are insufficient or unavailable, it is urged that these medical societies be guided in the development of these procedures by the ten principles adopted by the House of Delegates in 1934. The application of these ten principles to specific suggestions or proposals for the organization of medical services may be facilitated by utilizing the method of direct cash payments to individual members. Your committee unanimously concurs in the suggestion and recommends that the American Medical Association adopt the principle that in any place or arrangement for the provision of medical services the benefits shall be paid in cash directly to the individual member. Thus, the direct control of medical services may be avoided. Cash benefits only will not disturb or alter the relations of patients, physicians and hospitals.

Your committee has considered in detail that portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics under the heading "Group Hospitalization" and also the separate statement of the Bureau of Medical Economics entitled "Group Hospitalization Insurance." Your committee commends the clarity and forcefulness of these statements and recommends that the ten principles adopted in 1937 as the policy of the American Medical Association be amplified by the addition of the following statement to Principle 4:

If for any reason it is found desirable or necessary to include special medical services such as anesthesia, radiology, pathology or medical services provided by outpatient departments, these services may be included only on the condition that specified cash payments be made by the hospitalization organization directly to the subscribers for the cost of the services.

Disapproval of the inclusion of special medical services on a service basis in hospitalization insurance contracts will then be explicit but a constructive alternative arrangement will be possible.

Report of Committee on Legislative Activities: The report of the Committee on Legislative Activities indicates the large amount of work done and the many hours spent in the interest of organized medicine. The last paragraph reiterates the advice to members of county societies to scale their charges for professional services in accordance with local economic conditions. Your committee commends the industry of the Committee on Legislative Activities.

Resolutions on Program of Public Relations: The resolutions submitted by Dr. Lyell C. Kinney, California, were considered in joint session with the Reference Committee on Amendments to the Constitution and By-Laws. The result of the joint consideration will be reported by the Chairman of the Reference Committee on Amendments to the Constitution and By-Laws.

Respectfully submitted.

TERRY M. TOWNSEND, Chairman.
W. ALBERT COOK.
CHARLES A. DUKES.
HENRY C. MACATEE.
WALTER B. MARTIN.

On motions of Dr. Townsend, duly seconded and carried, the report of the Reference Committee on Legislation and Public Relations was adopted section by section and as a whole.

Report of Reference Committee on Hygiene and Public Health

Dr. Charles H. Goodrich, New York, acting for Dr. H. B. Everett, Chairman, presented the following report:

Your reference committee recommends that the Resolutions on Controlled Animal Experimentation, which had been introduced by Dr. Elbridge J. Best, California, be adopted after being amended to read as follows, and that the Board of Trustees be requested to undertake such measures as will make them most effective:

WHEREAS, The knowledge, possessed by modern medicine and the remedial measures made available for the prevention, diagnosis and treatment of disease in human beings, live stock and other domestic animals has been made possible only by controlled, humane, scientific animal experimentation, controlled by medical men, research workers and laboratories; and

WHEREAS, Controlled animal experimentation has uncovered the causes of contamination or blighting of many foods (fruits, vegetables, milk) which makes them dangerous for human and animal consumption; and

WHEREAS, Continuous research, study and investigation of causes and prevention of many human diseases, animal infections and causes for food deterioration are dependent on a continuation of controlled animal experimentation in order that human health and lives, as well as live stock and foodstuffs, may be saved and financial losses be prevented; and

WHEREAS, There are many poorly informed individuals now active in an endeavor to enact legislation that would cripple legitimately and humanely controlled animal experimentation, so vitally necessary to those scientific men who are seeking the etiology and prevention of conditions that still cause human suffering, kill fowl, other bird life and animals and affect the raising of foodstuffs; and

WHEREAS, These individuals, commonly known as antivivisectionists, willfully repudiate, ignore and misrepresent the proved facts that have been established by scientific research and study and persist in their efforts to mislead people in their endeavor to secure the enactment of laws prohibiting animal experimentation, which laws and prohibition would cause much human suffering, loss of lives and destruction of animals and foodstuffs and would also terminate the studies of scientists and laboratory research workers; therefore, be it

Resolved, By the American Medical Association: 1. That scientifically controlled animal experimentation is of supreme importance in the study and investigations seeking the cause and cure of factors and conditions that affect the health of and cause the death of human beings, animals, dogs, fowls, birds and live stock.

2. That any and all efforts to restrict or prohibit humanely controlled animal experimentation will cause untold suffering, loss of lives of human beings, animals and live stock and produce an incalculable financial loss to every community, industry and the commonwealth; and further be it

Resolved, That the American Medical Association condemns the efforts of all who endeavor to cripple scientific research by seeking to obtain the enactment of laws hampering or prohibiting the use of animals in research investigation; and further be it

Resolved, That the House of Delegates recommends that each unit of this Association be urged (1) to undertake immediately the education of the public on the need and value of competent animal experiments and (2) to expose the unjustifiable and insupportable claims and allegations of those who seek to obtain laws that may hamper or prohibit the humane use of animals in research studies.

Respectfully submitted.

H. B. EVERETT, Chairman.
CHARLES H. GOODRICH.
J. F. HASSIG.
CHARLES S. SKAGGS.
JOSEPH F. SMITH.

On motion of Dr. Goodrich, seconded by Dr. Robert A. Peers, California, and carried after discussion, the report of the Reference Committee on Hygiene and Public Health was adopted.

Report of the Reference Committee on Miscellaneous Business

Dr. Fred Moore, Chairman, presented the following report:

1. Resolution Dealing with Alcoholic Intoxication: Your committee sees much merit in the request as expressed in this resolution and recommends that it be transmitted to the Board of Trustees with the recommendation that the American Medical Association initiate studies for determination of definite, legally acceptable, scientific, clinical and laboratory tests for alcoholic intoxication. It further recommends that a report of said studies be presented to the House of Delegates at its next annual session.

2. Resolutions on Services of Section Delegates: Your reference committee was fortunate in having some of the section delegates meet with it for consideration of this resolution.

This petition is based on the following facts: 1. The existence of numerous societies of specialists wholly independent of the American Medical Association. 2. Occurrence of discussions and procedures in those societies which sometimes indicate a lack of understanding of the policies and procedures of this House. 3. A desire by sponsors of this resolution to correct these misunderstandings and substitute intelligent cooperation therefor.

Your committee is in complete accord with the desirable objectives of these resolutions and offers the following recommendations:

(a) That this House request delegates from the several sections to act as liaison between the House and those special societies whose scientific interests are included in the respective scientific sections of the American Medical Association which the delegates represent.

(b) That the Secretary of this House shall each year communicate with presidents and secretaries of all such societies as his judgment may dictate, for the purpose of identifying section delegates and reaffirming to these societies the desire of the American Medical Association for sympathetic cooperation in coordinating all medical interests and activities.

(c) That the Secretary of this House shall after each annual session communicate with the delegates from each section advising them regarding the desire of the House in this respect.

Respectfully submitted.

FRED MOORE, Chairman.
E. S. HAMILTON.
WALT P. CONAWAY.
F. S. CROCKETT.
E. L. HENDERSON.

On motions of Dr. Moore, duly seconded and carried, the report of the Reference Committee on Miscellaneous Business was adopted section by section and as a whole after discussion.

Report of Reference Committee on Amendments to the Constitution and By-Laws and Reference Committee on Legislation and Public Relations as a Joint Committee

Dr. H. A. Luce, Chairman of the Joint Committee, presented the following report, which was adopted on motion of Dr. Luce, seconded by Dr. A. A. Ross, Texas, and carried:

Your joint committee wishes to state at the outset that in its opinion there exists within the House of Delegates, all officers of the society and the entire membership of the organization complete harmony as to purposes and objectives, said purposes and objectives being better trained and better qualified physicians to the end that the American people may still continue the recipients of the highest quality of service. Furthermore, any apparent lack of harmony in the ranks of organized medicine is not based on truth but is due to attempts to discredit that large group who from the time of Aesculapius has contributed so much to human life and happiness.

Your joint committee has given careful and prolonged consideration to the proposed amendments to the By-Laws, presented by the delegation from the state of Michigan, proposing the creation of a committee on public relations, and the cognate resolutions presented by Dr. Lyell C. Kinney, California, requesting the Board of Trustees to employ professional public relations counsel, the proposed amendments and resolutions having the object of establishing a closer relationship between the public and organized medicine.

Delegates from the states of California, Massachusetts and New York spoke in support of the resolutions, and a number of other delegates appeared to denote their interest. Your committee also received from Dr. Austin A. Hayden, Secretary of the Board of Trustees, from Dr. Olin West, Secretary, from Dr. Morris Fishbein, Editor of THE JOURNAL, from Dr. W. C. Woodward, Director of the Bureau of Legal Medicine and Legislation, from Dr. W. W. Bauer, Director of the Bureau of Health Education, and from Dr. R. G. Leland, Director of the Bureau of Medical Economics, detailed information concerning the contacts and channels through which the public is constantly reached through agencies already in existence and in active operation. The joint committee was impressed with the importance of avoiding any innovation which might disturb these arrangements, which have been built up through the years and depend on many subtle and delicate personal relationships.

Your joint committee also considered the implications of the costs involved, together with the tax liabilities that might arise from any radical change in the methods of publicity maintained by the Association.

The foregoing considerations have led your committee to return the proposed amendments and resolutions without its approval. However, the committee feels impelled by reason of the sentiment revealed by the presentation of these proposed amendments and resolutions and the support of them from so many diverse quarters, as well as by common knowledge of the frequent unsatisfactory attitude of the press, to ask the House of Delegates to impress on the Board of Trustees its feeling that careful consideration should be given to the operation of our agencies of public information so that, on the one hand, the necessary *fortiter in re* may be preserved and, on the other, that certain deficiencies of *suaviter in modo* may be corrected.

Respectfully submitted.

For the Committee on Amendments to the Constitution and By-Laws:

H. A. LUCE, Chairman.
HERBERT L. BRYANS.
GEORGE P. JOHNSTON.
CHARLES J. WHALEN.
RAYMOND L. ZECH.

For the Committee on Legislation and Public Relations:

TERRY M. TOWNSEND, Chairman.
W. ALBERT COOK.
CHARLES A. DUKES.
HENRY COOK MACATEE.
WALTER B. MARTIN.

Resolutions on Status and Future of Army Medical Library and Museum

Dr. Roger Brooke, United States Army, asked and received the unanimous consent of the House to introduce the following resolutions, which were adopted on motion of Dr. Brooke, seconded by several and carried:

WHEREAS, The Congress of the United States passed an act which was approved by the President June 15, 1938, authorizing the construction of a new building to house the Army Medical Library and Museum at Washington, D. C.; and

WHEREAS, The Army Medical Library, commonly called the Surgeon General's Library, is now housed in an old building totally inadequate for the purpose, thus limiting the use of this most extensive and valuable collection of medical books and literature and subjecting it to extreme fire hazards; and

WHEREAS, This library, established more than a hundred years ago, and the museum more than seventy-five years ago, by the Surgeon General of the Army, have operated most efficiently under the Army Medical Department since their establishment and should so continue to operate; be it

Resolved, That the House of Delegates of the American Medical Association express its high appreciation to the Congress and the President of the United States for the recent enactment of legislation authorizing the construction of a new building for the Army Medical Library and Museum; and further be it

Resolved, That the House of Delegates petition the Congress of the United States and the President to make available as soon as practicable funds for the construction of a new building for the Army Medical Library and Museum.

Address of Dr. Charles M. Greenslade

The Speaker presented Dr. Charles M. Greenslade, Dunedin, New Zealand, representative of the New Zealand Branch of the British Medical Association, who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates of the American Medical Association:

Let me say that your welcome overcomes me. I come from a very small country. I represent the New Zealand branch of the British Medical Association and it is my privilege to accept your hospitality. We look more and more to the United States of America for advances in medicine and in surgery, and many of our men nowadays come to the United States to help themselves in the furtherance of their work. I deem it a great privilege to be here today and I thank you very much indeed for the way in which you have received me.

Remarks of Past President W. D. Haggard

Mr. Speaker, Gentlemen of the Association:

It is a very great pleasure to be with you here on this auspicious occasion. I am very happy that our colleague who speaks the mother tongue that we can almost understand is here in the capacity of our guest. We know of New Zealand and its contributions and the splendid membership it maintains in our profession. I am very happy to acknowledge on your behalf the greetings extended to you by our distinguished guest.

Remarks of Past President James S. McLester

Just one thing I can say to our British cousin that I said on another occasion, that is to tell him how we feel toward the British commonwealth of nations. A number of years ago right after the World War I was in the Panama Canal Zone looking over the fortifications with an army friend and I commented on the fact that the Pacific side was fortified so much better than the Atlantic side. I told him I wondered about that. He said, "Well, eventually the Atlantic side is going to be fortified just as well, but you must remember that on the Atlantic side we shall always have the British fleet."

Messages Condemning the Bombing of Hospitals and Red Cross Units

The Secretary read two telegrams, one received from the president of the China War Relief Association of America and the other from members of the medical staff of the Massachusetts General Hospital, as follows:

The Chinese people appeal to your convention to go on record in condemning the bombing of hospitals and Red Cross units in China by the Japanese air corps. The unwarranted destruction of lives and property engaged in discharging errands of mercy is growing every day and we

urge the medical profession in joining their colleagues in China in protesting against such atrocities.

B. S. FONG.

The undersigned members of the medical staff of the Massachusetts General Hospital, Boston, request that the American Medical Association, now assembled in convention at San Francisco, send a resolution from that body to the President of the United States to this effect: The A. M. A. strongly condemns the ruthless killing of innocent civilians in China by Japanese bombs and appeals to you to exert every possible pressure to stop not only this inhuman practice but also the continued flow of munitions, gasoline and scrap iron to Japan from our country.

ROY MINTZ.
D. L. SISCOE.
JOHN W. CASS JR.
M. T. EADES.
BENJAMIN TENNEY JR.

R. B. KING.
WILLIAM JASON MIXTER.
PAUL NORTON.
DONALD S. KING.
ARMIN KLEIN.
GEORGE W. VAN GORDER.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. John Q. Myers, North Carolina, and carried after discussion, that the House of Delegates go on record as disapproving the action of any country in bombing hospitals, Red Cross units and the helpless public.

ELECTION OF OFFICERS

Dr. Olin West, Secretary, on request of the Speaker, read Sections 1 and 3, Chapter IV, of the By-Laws referring to nominations.

Election of President-Elect

Dr. Joseph F. Smith, Wisconsin, nominated for President-Elect Dr. Rock Sleyster, Wauwatosa, Wis., and the nomination was seconded by Dr. W. E. Kittler, Illinois, for the Illinois delegation, and Drs. John W. Ames, Colorado; H. B. Everett, Tennessee; Walter E. Vest, West Virginia; Olin H. Weaver, Georgia; Tom B. Throckmorton, Section on Nervous and Mental Diseases; Burt R. Shurly, Section on Laryngology, Otology and Rhinology; William R. Molony Sr., California; C. W. Waggoner, Ohio; Frederick W. Meyer, Philippine Islands; Samuel P. Mengel, Pennsylvania; E. L. Henderson, Kentucky; J. W. Burns, Texas, and W. Albert Cook, Oklahoma.

Dr. W. H. Seemann, Louisiana, moved that the nominations be closed, and the motion was seconded by Dr. W. Albert Cook, Oklahoma, and carried unanimously.

Dr. J. W. Burns, Texas, moved that the Secretary be instructed to cast the unanimous ballot of the House for Dr. Rock Sleyster as President-Elect. The motion was seconded by Drs. H. B. Everett, Tennessee; J. Gurney Taylor, Wisconsin, and Tom B. Throckmorton, Section on Nervous and Mental Diseases, and carried unanimously.

The Secretary cast the unanimous vote of the House for Dr. Rock Sleyster, Wauwatosa, Wis., for President-Elect of the American Medical Association for the ensuing year, and the Speaker declared Dr. Sleyster so elected.

Election of Vice President

Dr. A. T. McCormack, Kentucky, addressed his remarks to the Vice Speaker, placing in nomination for Vice President the name of Dr. N. B. Van Etten, New York. The Speaker stated that there is a definite by-law which prohibits such a nomination.

Dr. A. A. Walker, Alabama, placed in nomination for Vice President the name of Dr. Howard Morrow, San Francisco, and the nomination was seconded by Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, and Dr. William R. Brooksher, Arkansas.

On motion of Dr. J. Newton Hunsberger, Pennsylvania, seconded by Dr. J. E. Paullin, Section on Practice of Medicine, and carried, the nominations were closed.

It was moved by Dr. E. G. Wood, Tennessee, that the Secretary be instructed to cast the unanimous ballot of the House for Dr. Howard Morrow as Vice President. The motion was seconded by Dr. A. T. McCormack, Kentucky, and carried.

The Secretary cast the unanimous vote of the House for Dr. Howard Morrow, San Francisco, for Vice President of the American Medical Association for the ensuing year, and the Speaker declared Dr. Morrow so elected.

Address of President-Elect Rock Sleyster

The Speaker presented the President-Elect, who addressed the House as follows:

Mr. Speaker, Members of the House:

I am going to ask you to be very charitable. I confess to being somewhat emotionally upset, and as you well know this great honor has come to me as a complete surprise. We are living in a very muddled world. One example of it: As we are gathered here some seven thousand strong to perfect ways and means of saving human life, a muddled world is spending billions and working feverishly in preparation for taking human life. It is a muddled world, inhabited by muddled people who are often given to muddled thinking, and I am wondering, Mr. Speaker, how much this picture may have influenced you in deciding to try psychiatric leadership.

The House of Delegates, representing nearly 110,000 American physicians, the only body authorized to speak for American medicine, formulates and voices the principles and policies which are necessary to insure to the American people the highest standards of medical care. Your officers and your Board of Trustees are charged with the responsibility of carrying out these policies in the interim between your deliberations. A newly elected executive can do little and say little except to affirm again his loyalty to those policies and to pledge you his best efforts in their behalf. It is this I promise you.

It is difficult to find words to express to you my appreciation of the great confidence you have placed in me. I am very happy, I am very proud, I am very humble in a realization of the responsibilities I shall assume a year hence. I pray that I may be given strength and courage and wisdom to meet the trust you have placed in me. There is so little to say except I shall do my best, and thank you.

Election of Secretary

Dr. A. T. McCormack, Kentucky, nominated Dr. Olin West, Chicago, to succeed himself as Secretary of the Association, and the nomination was seconded by Dr. Charles H. Goodrich, in behalf of the delegation from New York. The nominations were closed on motion of Dr. John Q. Myers, North Carolina, seconded by several and carried.

It was moved by Dr. J. D. Brook, Michigan, seconded by Dr. H. B. Everett, Tennessee, and carried, that the Speaker cast the ballot of the House for Dr. Olin West as Secretary.

The Speaker cast the ballot of the House for Dr. Olin West, Chicago, as Secretary of the American Medical Association, which was supported by a unanimous rising vote, and the Speaker declared Dr. West elected Secretary for the ensuing year.

Election of Treasurer

Dr. Arthur W. Booth, Chairman of the Board of Trustees, stated that the Board of Trustees nominated Dr. Herman L. Kretschmer, Chicago, as Treasurer. The nomination was approved by the House, and the Speaker declared Dr. Herman L. Kretschmer elected Treasurer for the ensuing year.

Election of Speaker of the House of Delegates

Dr. E. G. Wood, Tennessee, nominated for Speaker Dr. Harrison H. Shoulders, Nashville, Tenn. The nomination was seconded by Drs. H. B. Everett, Tennessee; Virgil Simpson, Kentucky; Charles A. Dukes, California; William H. Myers, Georgia; John Q. Myers, North Carolina; J. Gurney Taylor, Wisconsin; Howard L. Snyder, Kansas, and James E. Paullin, Section on Practice of Medicine.

Dr. James E. Paullin, Section on Practice of Medicine, moved that the nominations be closed, and the motion was seconded by several delegates and carried.

On motion of Dr. H. B. Everett, Tennessee, seconded by Dr. Charles W. Roberts, Georgia, and carried, the Secretary cast the unanimous vote of the House for Dr. Harrison H. Shoulders, Nashville, Tenn., for Speaker of the House of Delegates for the ensuing year, and Dr. Shoulders was declared duly elected Speaker of the House.

Election of Vice Speaker of the House of Delegates

The Speaker declared the next order of business to be the election of a Vice Speaker of the House of Delegates.

Dr. Junius B. Harris, California, nominated for Vice Speaker Dr. Edward M. Pallette, Los Angeles, and the nomination was seconded by Dr. Robert A. Peers, for the California delegation.

Dr. Fred Moore, Iowa, nominated for Vice Speaker Dr. Roy W. Fouts, Omaha, and the nomination was seconded by Dr. John W. Ames, Colorado.

Dr. Richard H. Miller, Massachusetts, nominated for Vice Speaker Dr. John M. Birnie, Springfield, Mass., and the nomination was seconded by Dr. William A. Ellingwood, Maine.

On motion of Dr. J. Newton Hunsberger, Pennsylvania, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, the nominations were closed, and the Speaker asked the tellers to spread the ballot.

The Secretary announced that 166 delegates had been recorded as present and that 162 votes had been cast, of which Dr. Edward M. Pallette received 42, Dr. Roy W. Fouts 95 and Dr. John M. Birnie 25.

On motion of Dr. John M. Birnie, Massachusetts, seconded by Dr. Junius B. Harris, California, and carried, the election of Dr. Roy W. Fouts, Omaha, as Vice Speaker of the House of Delegates for the ensuing year was made unanimous.

Appreciation of the Speaker, Dr. N. B. Van Etten

Dr. Charles H. Goodrich, New York, moved that the House of Delegates express its appreciation of the inspiration and thought, consideration and poise Dr. Van Etten had given it during his term as Speaker. The motion was seconded by Drs. W. H. Seemann, Louisiana; H. B. Everett, Tennessee, and George M. Fisher, New York, and carried.

Report of Council on Medical Education and Hospitals

Dr. Ray Lyman Wilbur, Chairman, presented the following report:

There seems to be some confusion in the minds of a good many of the Delegates and members of the Association as to the exact function of the Council on Medical Education and Hospitals and various other organizations now in the field both of education and of the hospitals. This is important, since we are going into a period of considerable experimentation, legislative and otherwise. It seemed desirable for you to remember that the Council has its power through the Association and that that power is largely a matter of publicity. Our relationship to the institutions that teach medical students is primarily based on the fact that we publish an approved list of those schools. That gives us a position of influence if not of power. We cannot tell those institutions what to do. Our relationship to the hospitals is largely because we have to do with the education of interns and of resident physicians and publish a list of approved hospitals for interns and residents, and also a list of hospitals on a register. Through THE JOURNAL, and particularly through the Directory which we publish, we have a direct relationship to practically all the physicians in the country.

There has come into the field in recent years the advisory board of the various specialties. That advisory board has entered on a study of graduate instruction through a commission supported by the various foundations. The chairman of that commission is Dr. W. C. Rappleye. There are two members of the Council on Medical Education and Hospitals on that commission. It is to study the philosophy of graduate instruction, not those institutions giving such instruction.

There is also in this field the American Hospital Association and the American College of Surgeons, and each hospital is apt to have a relation to these three bodies.

In connection with the advisory board on specialties we have assumed certain powers in regard to them by not joining this advisory board but asking that each board submit to the Council its constitution and its program for the approval of the Council. Some of those who were reluctant to do so found that our power largely consisted in our ability not to list them in the directory, so that I think we can say now that all of the special boards are in a direct relationship to the Council.

The hospital is becoming the center of experimentation in the fields of medical care. It is said that there are some 300 different propositions in different parts of the country, and what

goes on in the hospital is of enormous significance to us now as we approach this period when there is apt to be more and more in the way of legislative experimentation in this field.

There may be confusion between our Council and the American Hospital Association and the American College of Surgeons. We would like to have your continued support and an understanding with you that we as the representatives of the House of Delegates and the American Medical Association are in a position to take firm positions regarding certain of these propositions as they arise, and to seek the help of the other two associations. If you belong to the American College of Surgeons we ask you to help us bring about cooperation and coordination. If you are in the American Hospital Association we ask the same thing. If the medical profession in its relationship to these institutions is not a unit and not united, we are going to find ourselves in many difficulties that we can avoid by a well understood and well supported approach to these difficult questions.

I have made this statement in the hope that it would clarify for you just what is going on and so that it would leave in your minds the necessity of helping us represent you as the special problems come up, as they will, in connection not only with hospitals but with the medical schools. This is of vital importance in the field of graduate instruction, since, as I suggested the other day, we are now getting support from various sources, including the federal government, in some of these graduate courses, and what goes on there will have to go on largely through the hospitals and our relationship with those hospitals must be not only understood but backed if we are to take this common program forward. Thank you very much.

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the report of the Council on Medical Education and Hospitals be approved, and the motion was seconded by Dr. H. B. Everett, Tennessee, and carried.

Election of Trustees

The Speaker declared the next order of business to be the election of two Trustees, each to serve five years, to succeed Drs. Austin A. Hayden, Chicago, and Charles B. Wright, Minneapolis, whose terms expire this year.

Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, nominated Dr. Austin A. Hayden to succeed himself as a Trustee, and the nomination was seconded by Drs. G. Henry Mundt, Illinois; J. W. Burns, Texas; A. A. Walker, Alabama; Charles A. Dukes, California, and H. B. Everett, Tennessee.

The nominations were closed on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Charles H. Goodrich, New York, and carried, and the Secretary was instructed to cast the ballot of the House for Dr. Austin A. Hayden, Chicago, as Trustee, on motion of Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, seconded by Dr. John Z. Brown Sr., Utah, and carried.

The Secretary cast the unanimous ballot of the House for Dr. Austin A. Hayden to succeed himself as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. Hayden so elected.

Dr. W. F. Braasch, Minnesota, nominated Dr. Charles B. Wright, Minneapolis, to succeed himself as Trustee, and the nomination was seconded by Drs. J. E. Paullin, Section on Practice of Medicine; Charles W. Roberts, Georgia; J. Gurney Taylor, Wisconsin; Walter R. Steiner, Connecticut; E. L. Henderson, Kentucky; Felix J. Underwood, Mississippi, and J. W. Burns, Texas.

The nominations were closed on motion of Dr. George W. Kosmak, New York, seconded by Dr. W. H. Seemann, Louisiana, and carried.

On motion of Dr. J. D. Brook, Michigan, seconded by Dr. A. T. McCormack, Kentucky, and carried, the Secretary was instructed to cast the vote of the House for Dr. Charles B. Wright, Minneapolis, as Trustee.

The Secretary cast the unanimous vote of the House for Dr. Charles B. Wright, Minneapolis, to succeed himself as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. Charles B. Wright so elected.

Nominations for Standing Committees

Dr. Irvin Abell, President, submitted the following nominations for standing committees:

Judicial Council: Dr. John H. O'Shea, Spokane, Wash., to succeed himself, for a term ending in 1943.

Council on Medical Education and Hospitals: Dr. Frank H. Lahey, Boston, to succeed Dr. Frederic A. Washburn, who has given most efficient and excellent service and who desires to be released from further service, for a term ending in 1945.

Council on Scientific Assembly: Dr. James E. Paullin, Atlanta, Ga., to succeed himself, for a term ending in 1943.

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and carried, that the nominations be confirmed.

Election of Affiliate and Associate Fellows

The Secretary presented the following nominations for Affiliate and Associate Fellowship, which on motions duly seconded and carried, were confirmed by the House:

NOMINATIONS FOR AFFILIATE FELLOWSHIP

Collins, Homer C., Duluth, Minn.
Heyerdale, Oscar C., Rochester, Minn.
Hickling, D. Percy, Washington, D. C.
Olsen, Marie A., Chicago.
Ramsey, Russell T., Denver.
Stoll, John J., Chicago.

NOMINATIONS OF AMERICAN MEDICAL MISSIONARIES FOR ASSOCIATE FELLOWSHIP APPROVED BY THE JUDICIAL COUNCIL

Michener, Robert B., Kaimosi, Kisumu Kenya Colony, East Africa.
Thorne, George W., Pacific Grove, Calif.
Whitcomb, Elmer William, Baitalpur, C. P., India.

NOMINATIONS FOR ASSOCIATE FELLOWSHIP APPROVED BY THE SECTIONS INDICATED

LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

Ambrecht, Edward C., Wheeling, W. Va.

PATHOLOGY AND PHYSIOLOGY

Clawson, Benjamin J., Minneapolis.
Erlanger, Joseph, St. Louis.
Quigley, John P., Cleveland.
Rose, William C., Urbana, Ill.

PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

Miller, Ray Norris, Emporia, Kan.

Place of 1939 Annual Session

The Speaker announced that the next order of business was the selection of the place of the 1939 annual session.

Dr. G. Henry Mundt, Illinois, extended an invitation from the Chicago Medical Society and the Illinois State Medical Society to the American Medical Association to hold its 1939 annual session in Chicago.

Dr. Carl F. Vohs, Missouri, extended an invitation from the St. Louis Medical Society and the Missouri State Medical Association to the American Medical Association to meet in St. Louis in 1939. The invitation was supported by Dr. Floyd S. Winslow, for the delegates of the Medical Society of the State of New York, and by the Ohio delegation.

Dr. Francis F. Borzell, Pennsylvania, extended an invitation from Philadelphia, the Medical Society of the State of Pennsylvania and the medical schools in Philadelphia to the American Medical Association to meet in Philadelphia in 1939.

Dr. H. A. Luce, Michigan, extended an invitation from the state of Michigan, from Detroit and from the component county and constituent state medical societies to the American Medical Association to hold its 1939 annual session in Detroit. The invitation was supported by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology.

Dr. Walt P. Conaway, New Jersey, extended an invitation from the Medical Society of New Jersey and from the Atlantic County Medical Society to the American Medical Association to meet in Atlantic City in 1939.

Dr. Arthur W. Booth, Chairman, Board of Trustees, presented the following report: The following cities have sent invitations, within the limits according to our rules, and these are arranged

alphabetically: Atlantic City, Chicago, Cleveland, Detroit, Kansas City, Minneapolis and St. Paul, New York, Philadelphia, St. Louis.

New York has specifically asked to have the session of the American Medical Association in 1940; Minneapolis and St. Paul, Twin Cities, as well as Detroit and St. Louis in any of the three years 1939, 1940 or 1941.

On request of Dr. J. C. Flippin, Virginia, the Secretary presented a statement with respect to the facilities for holding the annual session of the American Medical Association in the cities that had sent invitations.

The Speaker announced that the American Medical Association had been invited to meet in 1939 in Chicago, St. Louis, Philadelphia, Detroit and Atlantic City. He asked the tellers to spread the ballot, and the Secretary announced that 167 delegates had been reported present and that 161 votes had been cast, of which Atlantic City received 29, Chicago 25, Detroit 10, Philadelphia 21 and St. Louis 76.

The Speaker announced that another vote would have to be taken since no city had received a majority of the votes and that in accordance with the rules the city receiving the smallest number of votes, namely, Detroit, would have to be dropped from the ballot. He added that he had been requested to announce that in order to expedite the vote Philadelphia would retire from the contest so that there would be three cities for which to vote: Chicago, St. Louis and Atlantic City.

The Secretary announced that 167 delegates had been reported present and that 143 votes had been cast, of which St. Louis received 93, Atlantic City 36 and Chicago 14, and the Speaker declared that the House of Delegates had selected St. Louis for the 1939 annual session of the American Medical Association.

Place of 1940 Annual Session

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, duly seconded and carried, the nominating speeches were limited to one minute each.

Dr. Francis F. Borzell, Pennsylvania, invited the American Medical Association to meet in Philadelphia in 1940, extending the invitation from Philadelphia, the Medical Society of the State of Pennsylvania and the medical schools in Philadelphia.

Dr. Frederic E. Sondern, New York, invited the American Medical Association to hold its 1940 annual session in New York City, and the invitation was supported by Dr. Carl R. Steinke, for the Ohio delegation, Dr. James R. McVay, for the Missouri delegation and Dr. Charles S. Skaggs, Illinois.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, regularly seconded and carried, the nominations were closed and the Speaker announced that New York, Philadelphia and Atlantic City were the cities placed in nomination for the 1940 annual session of the American Medical Association.

The Secretary announced that 167 delegates had been recorded present and that 132 votes had been cast, of which number New York received 83, Atlantic City 31 and Philadelphia 18, and the Speaker declared that the House of Delegates had selected New York City for the 1940 annual session of the American Medical Association.

Place of 1941 Annual Session

Dr. J. D. Brook, Michigan, extended an invitation to the American Medical Association to meet in Detroit in 1941.

Dr. Clyde L. Cummer, Section on Dermatology and Syphilology, extended an invitation from the Ohio State Medical Association and from the Academy of Medicine of Cleveland to the American Medical Association to hold its 1941 annual session in Cleveland and the invitation was supported by several delegates.

Dr. James T. Christison, Minnesota, in behalf of the Hennepin County Medical Society at Minneapolis, the Ramsey County Medical Society at St. Paul, and the Minnesota State Medical Association, invited the American Medical Association to hold its 1941 annual session in St. Paul-Minneapolis.

Dr. R. K. Packard, Illinois, invited the American Medical Association to hold its 1941 annual session in Chicago.

On motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Drs. George M. Fisher, New York, and Clyde

L. Cummer, Section on Dermatology and Syphilology, and carried, the nominations were closed, and the Speaker stated that Cleveland, Detroit, St. Paul and Minneapolis, and Chicago were the cities placed in nomination for the 1941 annual session of the American Medical Association.

The Secretary announced that 167 delegates had been recorded present and that 129 votes had been cast, of which Cleveland received 70, Chicago 27, Detroit 22, and St. Paul and Minneapolis 10, and the Speaker declared that the House of Delegates had selected Cleveland for the 1941 annual session of the American Medical Association.

Message of Appreciation

Dr. Irvin Abell, President, moved that the House of Delegates express, on behalf of the American Medical Association, sincere thanks and appreciation to the members of the California Medical Association, particularly to those residing in San Francisco, Oakland and the adjacent cities, and still more particularly to the chairmen of the various committees who had worked so hard for the comfort, pleasure and entertainment of the members of the Association; also to the press and to the most courteous citizens of this city as well as to the Woman's Auxiliary of the American Medical Association for their gracious hospitality extended during the session. The motion was seconded by Dr. Gunnar Gundersen, Wisconsin, and carried by a rising vote.

The House of Delegates adjourned sine die at 4:45 p. m.

REGISTRATION AT SAN FRANCISCO

The total registration at the San Francisco session, June 13 to 17, 1938, was 6,034. Below are given two summaries—one by states and one by sections:

Registration by States

Alabama	17	Nevada	38
Arizona	76	New Hampshire	4
Arkansas	13	New Jersey	38
California	3,143	New Mexico	13
Colorado	102	New York	205
Connecticut	22	North Carolina	10

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meeting.—The First Councilor District Medical Society was addressed in Paragould May 12 by Drs. John E. McGuire, Piggott, on scarlet fever; Thomas F. Hudson, Luxora, the black widow spider bite; Bonny M. Stevenson, Marion, the problem of syphilis; Robert H. Willett, Jonesboro, the relative value of high voltage roentgen therapy in uterine hemorrhages, and Martin E. Blanton, Jonesboro, eye injuries. Dr. Robert J. Haley, Paragould, gave the address of welcome.

CALIFORNIA

Mussel Quarantine.—The state department of health has established a quarantine on mussels from the southern boundary of Los Angeles County to the Oregon line, exclusive of San Francisco Bay. The quarantine prohibits the taking, sale or offering for sale of mussels growing within the designated area. It will continue through July, August and September.

State Medical Election.—Dr. Charles A. Dukes, Oakland, was chosen president-elect of the California Medical Association at its recent annual meeting in Pasadena and Dr. William W. Roblee, Riverside, was installed as president. Dr. George H. Kress, Los Angeles, was elected secretary-treasurer and director of public relations, succeeding Dr. Frederick C. Warnshuis, effective July 1, and reelected editor of *California and Western Medicine*.

DISTRICT OF COLUMBIA

Personal.—Capt. Samuel Ross Taggart, medical detachment, 260th coast artillery, District of Columbia National Guard, received the Soldier's Medal April 21 for heroism in rescuing a man from drowning at Virginia Beach, Va.—Mr. Theodore Wiprud, newly appointed executive secretary of the Medical Society of the District of Columbia, was guest of honor at a reception given by the society June 3.—Leland Wilbur Parr, Ph.D., has been promoted to professor of bacteriology at George Washington University School of Medicine.

GEORGIA

New Director of Division of Malaria.—Justin M. Andrews, Sc.D., associate professor of protozoology, School of Hygiene and Public Health, Johns Hopkins University, Baltimore, has been appointed director of the division of malaria investigation of the Georgia State Department of Health.

Special Society Elections.—Dr. Cornelius F. Holton, Savannah, was elected president of the newly organized Industrial Surgeons Association at its meeting in Augusta; Dr. Robert L. Rhodes, Augusta, is vice president and Dr. John W. Simmons, Brunswick, secretary-treasurer. The new society will meet jointly with the Insurance Claim Agents' Association of the state and the Georgia Manufacturers' Association in handling the problems of industrial claims.—Dr. Lewellyn H. Muse, Atlanta, was named president-elect of the Georgia Pediatric Society at its annual business meeting in Augusta. Dr. Charles Hall Farmer, Macon, was installed as president, succeeding Dr. Roger W. Dickson, Atlanta.

ILLINOIS

New Buildings at State Hospital.—A group of thirteen buildings was dedicated at the Dixon State Hospital, Dixon, May 20. The buildings were recently completed at a cost of \$1,250,000, financed by federal public works funds. Begun in 1927, the project includes an administration building, a nurses' home, two infirmaries, eight cottages for patients and a "maximum security" building or prison, it was reported. The cottages for patients are one story high, of brick, each unit being built in a series of wings. The new facilities will accommodate 1,200 additional patients.

Chicago

Competition Open for Prize.—The Institute of Medicine of Chicago announces that competition for the 1938 Joseph A. Capps Prize is open to graduates of Chicago medical schools who completed their internship or one year of laboratory work in 1936 or thereafter. The prize of \$400 is awarded for the

most meritorious investigation in medicine or in the specialties; investigation may also be in the fundamental sciences, provided the work has a definite bearing on some medical problem. Manuscripts should be submitted to the Institute of Medicine of Chicago, 86 East Randolph Street, not later than December 31.

Apprehend Robber of Pregnant Women.—Basil Lezak, 304 West Division Street, was arrested on the street June 3. Lezak, who was carrying a physician's bag, confessed to the police that he had been victimizing pregnant women under the representation that he was sent by the city or state health department, by some hospital in the vicinity or by the WPA to examine them. About two years ago he was placed on six months' probation for treating persons with medicine composed of some vegetable extract, it was reported. He was sentenced June 10 to six months in the house of correction on each of two counts of petty larceny.

INDIANA

Society News.—Dr. Roscoe L. Kleindorfer, Evansville, discussed "First Aid Treatment of Injuries and Burns" before the Knox County Medical Society in Vincennes recently.—At a meeting of the Monroe County Medical Society in Bloomington Dr. Paul Merrell, Indianapolis, spoke on "Thoracic Surgery."—A recent meeting of the Hancock County Medical Society was addressed in Greenfield by Dr. Martin H. Fischer, Cincinnati, on "Physiologic Treatment of Heart Disease."—The Tippecanoe County Medical Society was addressed in Lafayette recently by Dr. Harry E. Mock, Chicago, on "Conservative Treatment of Gallbladder and Appendicitis."—Dr. Harold M. Trusler, Indianapolis, discussed "Treatment of Extensive Burns" before the Delaware-Blackford Medical Society in Muncie recently.—At a meeting of the Henry County Medical Society in Newcastle Dr. James H. Stygall, Indianapolis, spoke on pneumothorax.—Dr. Stanley P. Reimann, Philadelphia, discussed "The Diagnosis of Secondary Breast Tumors and Relation of Hormones to Cancer" before a joint meeting of the Fort Wayne and St. Joseph county medical societies in Fort Wayne recently. He conducted a clinic in the afternoon and addressed a public meeting in the evening.—The Gibson County Medical Society was recently addressed in Princeton by Dr. Laman A. Gray, Louisville, Ky., on "Leukorrhea and Office Gynecology."

IOWA

Smallpox Regulations Revised.—Regulations by the state department of health about smallpox have been revised to place primary emphasis on successful vaccination or revaccination and on isolation of active cases and of susceptible persons. The new regulations permit the breadwinner to enter and leave his home to continue the support of his family, provided he shows definite evidence of immunity to smallpox. Persons having the disease will be isolated for a minimum period of fourteen days. Children who have been exposed to smallpox but who have not been successfully vaccinated, previously or within seventy-two hours after initial exposure, will be isolated for a minimum period of twenty-one days. It is expected that the new regulations will increase attention to specific means of prevention, applied early in life and repeated before and after admission to school. During the thirty year period 1908-1937, officially reported cases of smallpox in Iowa totaled 50,303; of these 207 persons died.

LOUISIANA

Society News.—The Orleans Parish Medical Society was addressed June 13 at the U. S. Marine Hospital, New Orleans, by P. A. Surg. Paul E. Walker on "Pontocaine Anesthesia"; P. A. Surg. Joseph G. Pasternack, "Unusual Bone Tumors"; and P. A. Surgeon (R.) Henry D. Stroupe and Asst. Surg. (R.) William M. Boles, "Treatment of Corneal Ulcer with Fever Therapy." The society was addressed May 9 by Drs. Edwin A. Socola on "Banana and Banana Powder Therapy in Diarrheal Diseases of Infants and Young Children"; Dean H. Echols, "Ruptured Intervertebral Disk as a Cause of Sciatic Pain," and Leo N. Elson, "Treatment of Tularemia."

MARYLAND

Dr. Maxcy Joins Epidemiology Department at School of Hygiene and Public Health.—Dr. Kenneth F. Maxcy has resigned as professor and head of the department of bacteriology at Johns Hopkins University School of Hygiene and Public Health to become professor and head of the department of epidemiology. Dr. Maxcy joined the Johns Hopkins staff in 1937 after resigning as professor and head of the department of preventive medicine and public health at the University of

Minnesota Medical School, Minneapolis. He graduated from the Johns Hopkins school of medicine in 1915. He is a scientific director of the International Health Division of the Rockefeller Foundation.

MICHIGAN

Personal.—Dr. Anthony J. J. Rourke, assistant superintendent, Vanderbilt Clinics, Presbyterian Hospital-Columbia University Medical Center, New York, has been appointed assistant director of the University Hospital, Ann Arbor, succeeding George P. Bugbee, who will become superintendent of the Cleveland City Hospital. The change was effective July 1.

Changes at the University.—The following promotions at the University of Michigan Medical School, Ann Arbor, were recently announced:

Dr. Herman M. Pollard to assistant professor of internal medicine.
Dr. Lloyd F. Catron to assistant professor of pathology.
Dr. Cameron Haight to associate professor of surgery.
Dr. Jerome W. Conn to assistant professor of internal medicine.
Dr. Isadore Lampe to assistant professor of roentgenology.

New Institute for Neuropsychiatry.—Ground has been broken for the new Neuropsychiatric Institute at the University Hospital, Ann Arbor. The building will be in the form of a wing to the north of the University Hospital and will be connected to the main building by corridors. The main section will be five stories high, flanked on each end by pavilions three stories high. The fourth floor of the new building will be on the level of the first floor of the main hospital. Provision will be made for the care of sixty-three adults and twenty children. There will be facilities for occupational therapy, physical therapy and hydrotherapy. The neuropathologic and research laboratories will be on the first floor of the new building. According to the *University Hospital Bulletin* the new unit is designed to form a center for the diagnosis, care and active treatment of forms of incipient mental disease which are not likely to receive adequate care until a state of more profound disability is reached. Only patients who are ready to come on a voluntary basis are treated, entering through the regular admitting department of the University Hospital.

MINNESOTA

Society News.—Chauncey Leake, Ph.D., San Francisco, gave a Mayo Foundation lecture at the Mayo Clinic, Rochester, June 6 on "Pharmacologic Aspects of Central Nervous System Activity." Dr. Owen H. Wangenstein, Minneapolis, gave a lecture May 19 at the clinic on "The Problem of Therapy in Acute Intestinal Obstruction."

Personal.—Dr. Frank C. Mann, Rochester, received the honorary degree of doctor of laws from his alma mater, Indiana University, Bloomington, Ind., at its commencement exercises June 13, at which he delivered the annual address. Dr. Mann will deliver a lecture before the Royal College of Surgeons, London, in July on "The Etiology of Peptic Ulceration."—Dr. Ralph X. Rossen, St. Peter, has been appointed superintendent of the state hospital at Hastings to succeed William J. Yanz, who has resigned after thirty-eight years' service. The change was effective June 30.

Ten Years for Illegally Obtaining Morphine.—Katherine Burkhardt pleaded guilty June 8 to a charge of obtaining morphine by fraud, deceit, misrepresentation and subterfuge and was sentenced to a term of not to exceed ten years in the Women's Reformatory at Shakopee. A drug addict, the defendant is the first person to be prosecuted for obtaining morphine by fraud or misrepresentation under the Minnesota Uniform Narcotic Drug Act, passed in 1937. The maximum penalty for a violation of the act is five years' imprisonment in a state penal institution. In this case the defendant received a ten year sentence because she had two prior convictions for felonies in the U. S. District Court. The woman obtained nineteen prescriptions for a total of 233 1/4 grain morphine sulfate tablets from six Minneapolis physicians between March 26 and 30. She obtained these prescriptions by misrepresenting her physical condition and falsifying her name and address. She used many aliases in obtaining the prescriptions. She stated that her maiden name was Mahoney, that her married name was Burkhardt and that she had been divorced in 1926. She admitted that she had been addicted to the use of morphine for sixteen years. She claimed that she suffered from chronic asthma, that she had a tumor on her spine and suffered from adhesions following an operation. In 1933 the defendant was sentenced in the federal court in Minneapolis to a three year term in the Federal Industrial Institution for Women at Alderson, W. Va., for violation of the Harrison Narcotic Act; in 1936 she was sentenced in the federal court at St. Paul to serve ten months in the Minneapolis Work House for a similar offense.

MISSISSIPPI

Changes in State Department of Health.—Dr. Henry C. Ricks, for ten years director of county health work of the state department of health, Jackson, has been appointed director of the state hygienic laboratory, effective May 1, following the retirement of Dr. Theodore W. Kemmerer. Dr. John A. Milne will succeed Dr. Ricks as director of county health work and continue to serve in his present position as director of maternal and child welfare division and health education. Dr. Kemmerer has served as director of the hygienic laboratory for fourteen years.

MISSOURI

Physician Given Civic Award.—Dr. Avery P. Rowlette, medical director of City Hospital and assistant professor of clinical surgery, Washington University School of Medicine, St. Louis, was presented May 19 with the distinguished service award of the U. S. Junior Chamber of Commerce for outstanding civic service in St. Louis during 1937. The award, a gold key, is given annually to a St. Louisan under 36 years of age who is chosen by the Young Men's Division of the chamber of commerce. Dr. Rowlette was cited for his work on the new psychopathic clinic now under construction, the new Homer G. Phillips Hospital for Negroes, and his services as medical director during the Southeastern Missouri floods in the early part of 1937. He graduated at Washington University School of Medicine in 1929.

Society News.—Dr. Charles T. Reid, Joplin, discussed "Tinnitus Aurium" before the Jasper County Medical Society in Joplin recently.—At a meeting of the Cooper County Medical Society recently Dr. Eugene P. Hamilton, Kansas City, spoke on "Diagnosis and Treatment of Appendicitis" and Dr. Dudley S. Conley, Columbia, "Some Problems of Our Medical Organizations." Dr. Conley addressed a recent meeting of the Ninth Councilor District Medical Society at Rolla and Dr. Edwin Lee Miller, Kansas City, "Hepatorenal Syndrome in Relation to the Liver Death." The society was the guest of the Phelps-Crawford County Medical Society.—The Trudeau Club, St. Louis, was addressed May 5, among others, by Dr. Israel J. Flance on "Postmortem Incidence of Tracheobronchitis."—Dr. Roscoe L. Sensenich, South Bend, Ind., discussed "The Social Aspects of Sickness" before the Jackson County Health Forum recently in Kansas City.

NEBRASKA

Honorary Members of State Association.—At a meeting of the council of the state medical association the following were voted honorary members: Drs. Rudolph Rix, Omaha; Don F. Morris, Lewellen; Arthur E. Cook, Randolph; Martin L. Sparks, Bloomington; John A. Waggener, Humboldt, and George J. Rubelman, Tecumseh.

Society News.—At a meeting of the Omaha-Douglas County Medical Society recently Drs. Perrin H. Long, Baltimore, discussed sulfanilamide and Willis D. Wright, Omaha, "The Anemias Associated with Hypothyroidism."—A symposium on cancer was presented before the Dawson County Medical Society in Lexington recently by Drs. Howard B. Hunt, James Perry Tollman and Charles W. McLaughlin Jr., all of Omaha. Dr. McLaughlin also discussed surgery in children.—Dr. William J. Arrasmith, Grand Island, addressed the Four County Medical Society in Spalding May 5 on goiter.—The Platte-Loup Valley Medical Society was addressed at Columbus May 11 by Dr. James E. M. Thomson, Lincoln, on "Fractures of the Foot and Ankle."

Annual Assembly.—The sixth annual assembly of the Omaha Mid-West Clinical Society will be held at the Hotel Paxton, Omaha, October 24-28. In addition to lectures by members of the faculties of Creighton and Nebraska universities, the guest speakers will include:

Dr. Henry L. Bockus, Philadelphia, medicine.
Dr. Robert T. Frank, New York, gynecology and obstetrics.
Dr. Cameron Haight, Ann Arbor, surgery.
Dr. Louis J. Hirschman, Detroit, surgery.
Dr. Edward L. Jenkinson, Chicago, radiology.
Dr. Foster Kennedy, New York, neurology.
Dr. Gordon B. New, Rochester, Minn., otolaryngology.
Dr. Oliver S. Ormsby, Chicago, dermatology.
Dr. Oliver H. Perry Pepper, Philadelphia, medicine.
Dr. Heyworth N. Sanford, Chicago, pediatrics.
Dr. Alfred R. Shands Jr., Wilmington, Del., orthopedic surgery.

A symposium on anesthesia will be presented by Drs. John S. Lundy, Rochester; Kenneth C. McCarthy, Toledo; Archibald Ross McIntyre, Omaha; John A. Moffitt, Oklahoma City, and Ralph M. Waters, Madison, Wis.

NEW HAMPSHIRE

Industrial Survey.—The state board of health announced in its May bulletin that a preliminary study of industries in New Hampshire with reference to occupational disease is in progress. The survey is the result of a recommendation made in the report of the Commission for the Study of Occupational Diseases in New Hampshire to the governor in 1937. It is the purpose of the study to obtain information concerning the environment associated with the various occupations which potentially may have an effect on the health of employees. The commission was formed in 1935.

NEW JERSEY

Hospital News.—A three months graduate course in gynecology and obstetric pathology is being conducted at the Margaret Hague Maternity Hospital, Jersey City, by Dr. Nicholas M. Alter and his associates. The Hospital of St. Barnabas, Newark, dedicated a new six story extension recently; the new addition accommodates eighty beds, operating, x-ray and maternity facilities and offices.

NEW YORK

Society News.—Dr. Fred W. Geib, Rochester, discussed "Brain Trauma" before the Medical Society of the County of Monroe at a meeting May 19. At a meeting of the society May 17 Dr. Arthur C. Christie, Washington, D. C., spoke on "Modern Trends in Medicine with Special Reference to Hospital Insurance."

Outbreak of Dysentery.—Seventy-one cases of gastrointestinal illness are known to have occurred between May 17 and 31 in two adjacent villages in Albany County, according to *Health News*. Specimens submitted from three persons during the acute stage yielded dysentery bacilli of the Sonne type. Water from the system which supplied both villages was found to be the one factor common to all cases. The water supply is taken from a creek and treated by chlorine but not filtered. Interruption in chlorination of the water was reported to have occurred on at least one occasion preceding the outbreak. Coincident with the failure of chlorination, a heavy rainfall also increased pollution of the source of supply.

Personal.—Dr. Karl Fischel, superintendent and medical director of the Will Rogers Memorial Hospital, Saranac Lake, N. Y., for four years, has resigned. Oskar Baudisch, director of the research division, Saratoga Springs Commission, State of New York, has been appointed associate in biochemistry at the Albany Medical College; he will continue his connection with the commission. Dr. Willard H. Sweet was guest of honor at a dinner in Croton, April 18, given by the medical board of Peekskill Hospital to mark his retirement as president of the board. Dr. William S. Bainbridge, New York, was the guest speaker. Dr. Otto Pfaff, Oneida, was recently honored by Oneida friends with a testimonial dinner on completion of fifty years of medical practice. James H. Foster, director of the child aid bureau of the state social welfare department, Albany, died May 9; he had served thirty years in the state's employ. Mrs. Elizabeth Wilnot Newcomb, founder and first president of the Stony Wold Sanatorium, Lake Kushaqua, died May 30, aged 78. Mrs. Newcomb was instrumental in raising funds to build a cottage at the Trudeau Sanatorium, Saranac Lake, but on the advice of the late Dr. Edward L. Trudeau she purchased and remodeled as a sanatorium an old country hotel at Lake Kushaqua. It was incorporated as the Stony Wold Sanatorium in 1901.

New York City

Dr. Hammarsten Gives Janeway Lectures.—Einar Hammarsten, professor of chemistry, Caroline Medical and Surgical Institute, Stockholm, Sweden, gave the Edward Gamaliel Janeway Lectures at the Mount Sinai Hospital of New York, May 24, on "Duodenum and Its Associates, the Important Hormonal Centrum" and May 26, "Cell Structure: Functions of Nucleic Acid."

Changes at New York University.—Dr. Thomas A. Gonzales, chief medical examiner of the city, has been promoted from associate professor to professor of forensic medicine at New York University College of Medicine. Other promotions include those of Wendell J. S. Krieg, Ph.D., to assistant professor of anatomy and David Wechsler, Ph.D., assistant clinical professor of psychiatry.

Dr. Howard Fox Becomes Professor Emeritus.—Dr. Howard Fox has retired as professor of dermatology and syphilology at New York University College of Medicine with the title of professor emeritus. He had been associated with

the school since 1925. Dr. Fox was born in London, England, July 4, 1873; he received his degree in medicine at Columbia University College of Physicians and Surgeons in 1898 and later took graduate work in Berlin and Vienna. He taught at Dartmouth Medical College and the New York Polyclinic Medical School. During the World War he was commanding officer of base hospital number 136, Vannes, France. He served as president of the American Dermatological Association and of the American Board of Dermatology and Syphilology and in 1935 as honorary president of the ninth International Congress of Dermatology, Budapest. A testimonial dinner in his honor was held at Sherry's recently.

Personal.—Mary B. Stark, Ph.D., professor and head of the department of histology and embryology at the New York Medical College and Flower Hospital, received the honorary degree of doctor of science from Hamline University, St. Paul, June 6. Dr. Herbert W. Wade, medical director, Leonard Wood Memorial in the Philippine Islands, was the guest of honor May 1 at a dinner given by the medical advisory board of the memorial at the Union League Club. The speakers included Frank R. McCoy, major general, U. S. Army, Washington, D. C., and Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Dr. Wilbur A. Sawyer and Perry Burgess. The staff of Mount Sinai Hospital, New York, gave a dinner June 2 to Dr. Israel Strauss in celebration of his sixty-fifth birthday and "in honor of his many years of distinguished service in the hospital and the profession," according to *Science*. Dr. Jose Arcé, professor of surgery, University of Buenos Aires, was elected to honorary membership in the Medical Society of the State of New York at its recent annual meeting. Dr. George Gray Ward, who retired in April as chief surgeon of the Woman's Hospital, was presented with a silver bowl at a recent reception in his honor; he has been made chief surgeon emeritus and consulting surgeon of the hospital. Dr. Rufus I. Cole was honored recently at a dinner at the Rockefeller Institute for Medical Research; he was presented with a bound set of volumes of reprints from the institute hospital, from which he resigned as director last year. Dr. Max Pinner, Ithaca, has been appointed chief of the division of pulmonary diseases at Montefiore Hospital, effective September 1.

NORTH CAROLINA

Changes at State Hospital.—Dr. John McCampbell, superintendent of the State Hospital, Morganton, has resigned from the position after thirty years of service and has been succeeded by Dr. Fonso B. Watkins, first assistant physician for twenty-six years. Dr. McCampbell was the second superintendent to head the hospital since its founding in 1883. The new superintendent is a native of North Carolina and a graduate of Jefferson Medical College, Philadelphia. Dr. Roy H. Long, a member of the medical staff, has been appointed to succeed Dr. Watkins with the title of assistant superintendent, and Dr. John R. Saunders, Lewiston, formerly a member of the staff, was appointed to fill the vacancy made by the changes.

OHIO

Graduate Day.—The Columbus Academy of Medicine sponsored a graduate day at the Scioto Country Club, Columbus, June 2. A golf tournament preceded the scientific program; speakers in the latter included:

Dr. Walter C. Alvarez, Rochester, Minn., Some Fairly Common but Usually Unrecognized Causes of Abdominal Discomfort.

Dr. Roy D. McClure, Detroit, Acute Pancreatitis.

Dr. Charles E. Galloway, Evanston, Ill., Prevention and Treatment of Puerperal Fever.

These speakers also addressed the evening session: Dr. Alvarez, "Constipation and Diarrhea"; Dr. McClure, "Modern Treatment of Burns," and Dr. Galloway, cervical lesions and an exhibit of colored photography of the cervix.

District Meetings.—The Eighth Councilor District Medical Society were guests of Dr. Louis Mark and the Rocky Glen Sanatorium at McConnellsville, June 23, for the annual midsummer meeting. The speakers included Drs. Louis J. Roth, Columbus, on "Educational Campaign Against Syphilis in Columbus" and George W. Crile, Cleveland, "Clinical Aspects of Essential Hypertension and Recurrent Hyperthyroidism." The Second Councilor District of the Ohio State Medical Association held a meeting in Dayton recently. The guest speakers were Drs. Claire L. Straith, Detroit, who spoke on "Crossroad Surgery" and "Plastic Surgery of the Head and Face"; Pascal Brooke Eland, Philadelphia, on "Prevention of Uterine Cancer," and Gerald S. Shibley, Cleveland, "Diagnosis and Treatment of Pneumonia." Dr. John B. Alcorn, Columbus, president of the state association, and Mr. Charles S. Nelson, Columbus, executive secretary, spoke on organization activities.

OREGON

Hospital News.—Plans are under way to present the sanatorium now under construction at McCredie Hot Springs to the University of Oregon as soon as the buildings are finished.

Plague Infection.—Plague infection has been proved in tissue from one *Citellus oregonus* found dead April 23, 7 miles northwest of Hereford, Baker County, according to *Public Health Reports*. It was also proved in fifty-one fleas collected May 2 from eighty-eight of the squirrels in the same region.

PENNSYLVANIA

District Meetings.—The first annual meeting of the Twelfth Councilor District Medical Society was held in Dallas June 29. The speakers included Drs. Chauncey L. Palmer, Pittsburgh, on "Concentrating on Constructive Public Health Activities" and Charles H. Goodrich, Brooklyn, "Prevention of Injuries and Chronic Diseases and the Economics Related Thereto." —At the annual meeting of the Fourth Councilor District Medical Society in Pottsville June 30 the speakers included Dr. Emil Novak, Baltimore, on "Use of Endocrine Substances in Treatment."

Philadelphia

Personal.—Dr. William Egbert Robertson has been appointed chief medical director of the Northeastern Hospital and Dr. Alexander Silverstein consulting neurologist.

Changes at Jefferson Medical College.—Dr. James Torrance Rugh has retired as professor of orthopedic surgery at Jefferson Medical College and has been named professor emeritus and consulting orthopedic surgeon to the college hospital. Dr. Rugh graduated at Jefferson in 1892. He has been a member of the orthopedic faculty at his alma mater for forty-six years. In 1934 the senior class of the college presented a portrait of Dr. Rugh to the college. The following changes in the faculty during the past session are reported among others:

Dr. John B. Flick, clinical professor of surgery.
Dr. Lewis C. Scheffey, clinical professor of gynecology.
Dr. B. B. Vincent Lyon, associate professor of medicine.
Dr. Garfield G. Duncan, assistant professor of medicine.
Dr. Abraham Cantarow, assistant professor of medicine.
Dr. Victor G. Haury, assistant professor of pharmacology.
Dr. Baxter L. Crawford, assistant professor of pathology.

Pittsburgh

Society News.—Dr. Herbert Windsor Wade, Culion, P. I., addressed the Pittsburgh Academy of Medicine May 6 on "Leprosy as a World Problem." Dr. Harry M. Little, among others, addressed the academy recently on "The Child Guidance Center: Its Sphere of Usefulness to the Medical Profession." —The Allegheny County Medical Society was addressed May 17 by Drs. Thomas L. McCullough on "Treatment of Acute Suppurative Fulminating Fronto-Ethmoiditis" and Roy R. Snowden, "Allowing for Physiological Adjustment in Establishing the Diet in Diabetes Mellitus." —At a meeting of the General Health Council in Pittsburgh May 12 Dr. Thomas Parran, Washington, D. C., surgeon general, U. S. Public Health Service, spoke on "Venereal Disease Control" and Mr. Bleecker Marquette, executive secretary, Health Federation of Cincinnati, "The Community Value of a Health Council."

SOUTH CAROLINA

State Medical Election.—Dr. Douglas Jennings, Bennettsville, was chosen president-elect of the South Carolina Medical Association at its annual meeting in Myrtle Beach May 17-19 and Dr. James R. Des Portes, Fort Mill, was installed as president. Dr. George E. Thompson, Spartanburg, was chosen vice president, and Dr. Edgar A. Hines, Seneca, was reelected secretary-treasurer. The 1939 session will be held in Spartanburg.

SOUTH DAKOTA

Personal.—Dr. Edmund Stephen Donohue, Gregory, has been appointed superintendent of the Gregory County Board of Health.

Meeting of Academy of Science.—Ward L. Miller, Ph.D., State College, Brookings, was elected president of the South Dakota Academy of Science at its annual meeting at Yankton College recently. Vice presidents are Walter V. Searight, Ph.D., Vermillion, and Alvin L. Moxon, State College. Arthur L. Haines, A.M., Vermillion, is the secretary. David D. Whitney, Ph.D., professor of zoology, University of Nebraska, was the guest speaker; his subject was "Heredity in Man."

TENNESSEE

Dr. G. Canby Robinson Honored.—A dinner in honor of Dr. G. Canby Robinson, Baltimore, was given, June 7, by members of the faculty of Vanderbilt University School of Medicine, Nashville, where Dr. Robinson served as dean from 1921 to 1929. Dr. Charles Sidney Burwell, dean, Harvard University Medical School, Boston, and formerly head of the department of medicine at Vanderbilt, was toastmaster. A portrait of Dr. Robinson, painted by Thomas Corner of Baltimore, was presented to the university on behalf of friends, by Dr. Ernest W. Goodpasture, professor of pathology. The portrait will be hung in the school of medicine. A book of clippings and photographs showing the progress of the school from its founding until the present, and including signatures of all guests at the dinner, was presented to Dr. Robinson. The speakers included Drs. Waller S. Leathers, dean of the school, William H. Witt, Hugh J. Morgan and Glenn E. Cullen, Ph.D., director of the Pediatric Research Institute of Cincinnati and formerly professor of chemistry at Vanderbilt.

TEXAS

Hospital News.—Dr. Elmer W. Jones, Wellington, who has owned and operated the Wellington Hospital for many years, recently gave the entire plant to the Sisters of St. Dominic, it is reported. —The George A. Griffith Memorial Hospital, a unit of the Sanatorium of Paris, was dedicated recently. The new building, constructed at a cost of \$50,000, will be used for children up to 15 years of age.

VIRGINIA

Society News.—Drs. Chevalier Jackson and John A. Kolmer, Philadelphia, addressed the Roanoke Academy of Medicine recently on "Diverticulum of the Hypopharynx" and "Infection, Immunity and Specific Treatment of Lobar Pneumonia" respectively.

Portrait of Dr. Flippin.—An oil painting of Dr. James Carroll Flippin, dean and professor of internal medicine, University of Virginia Department of Medicine, Charlottesville, has been presented to the university by the alumni, and the graduating class of 1938. The portrait was presented by Mr. James B. Black, president of the senior medical class. Dr. Flippin received the honorary degree of doctor of science from the university at its commencement exercises June 7.

Personal.—Dr. Harold W. Kinderman, Wicomico Church, retired in 1936 from the U. S. Army Medical Corps, has been appointed superintendent of Dixie Hospital, Hampton. —Dr. Ennon S. Williams, Richmond, was recently appointed medical director of the Life Insurance Company of Virginia, succeeding the late Dr. Charles L. Rudasill. —Alton D. Brashear Jr., D.D.S., instructor in anatomy at Louisiana State University Medical Center, New Orleans, has been appointed an assistant professor of anatomy at the Medical College of Virginia. —Dr. Charles L. Savage, Charlottesville, recently director of the health unit for Tazewell, Russell and Buchanan counties, has been appointed director of the Hanover County health unit with headquarters in Ashland.

WEST VIRGINIA

Obstetric Pilgrimage.—The annual pilgrimage of the West Virginia Obstetrical and Gynecological Society to a recognized medical center was recently held in Cleveland. One day of specialized clinics was spent at each of the following: Maternity and St. Luke's hospitals and the Cleveland Clinic. The next session of the society, its fourth, will probably be held in either Cincinnati or Pittsburgh.

State Medical Meeting at White Sulphur Springs.—The seventy-first annual meeting of the West Virginia State Medical Association will be held in White Sulphur Springs July 11-13 under the presidency of Dr. Charles W. Waddell, Fairmont. Guest speakers will be:

Dr. Horace M. Korns, Iowa City, The Nature and Manifestations of Congestive Heart Failure.
Dr. Waltman Walters, Rochester, Minn., Hyperfunctioning Lesions of the Ductless Glands.
Dr. Louis H. Clerf, Philadelphia, Pulmonary Suppuration.
Dr. John C. Gittings, Philadelphia, Nonspecific Lung Infections.
Dr. Gordon F. McKim, Cincinnati, Nephropathy.
Dr. Henry S. Ruth, Philadelphia, Advantages Offered by an Organized Anesthetic Service.
Dr. Edward L. Compere, Chicago, Errors in Diagnosis or Treatment for Low Back Pain.
Dr. Nicholson J. Eastman, Baltimore, Pyelitis in Pregnancy.
Dr. Irvin Abell, Louisville, Ky., President of the American Medical Association, Surgical Treatment of Peptic Ulcer.

Dr. Cecil B. Pride, Morgantown, will deliver the oration on surgery on "Injuries of the Knee Joint," and Dr. Charles B. Chapman, Welch, the oration on medicine on "Human Blood

as a Therapeutic Agent." The West Virginia Industrial Physicians and Surgeons Association will meet Sunday evening July 10 with Dr. George H. Gehrmann, Wilmington, Del., as the guest speaker on "Industrial Medicine and Toxicology." The West Virginia Heart Association will meet Monday afternoon July 11 with Dr. Kornas as the guest speaker on "The Effect of Pulmonary Emphysema on the Heart." The West Virginia Obstetrical and Gynecological Society will hold its annual meeting Thursday with Dr. Eastman as the guest speaker on "Pregnancy and Labor in the Bicornate Uterus." The annual convention banquet will be Wednesday evening.

Graduate Courses in Obstetrics and Pediatrics.—The West Virginia State Medical Association is sponsoring refresher courses in obstetrics and pediatrics to begin July 18 in two circuits. The courses will be given one day each week in each town for five consecutive weeks. The circuit in the northern part of the state will include the towns of Martinsburg, Keyser, New Martinsville, Weston and Fairmont; the southern circuit will consist of Logan, Welch, Beckley, Ronceverte and Fayette. Drs. Louis H. Douglass and Thomas Campbell Goodwin, Baltimore, will lecture on obstetrics and pediatrics, respectively, for the northern group; Drs. William F. Mengert, Iowa City, on obstetrics, and Lee Palmer, Louisville, Ky., on pediatrics in the southern towns. During the past two years these courses have been sponsored by the state health department.

GENERAL

Examination in Ophthalmology Postponed.—The American Board of Ophthalmology announces that the examination previously scheduled for November 15 at Oklahoma City has been canceled. Examinations are scheduled for New York October 7 and Washington, D. C., October 8.

Research Fellowships Available.—The Finney-Howell Research Foundation, Inc., Baltimore, announces that applications for fellowships next year must be in the hands of the foundation by Jan. 1, 1939. The appointments will be made the following March. Dr. William A. Fisher, 1211 Cathedral Street, Baltimore, is secretary of the foundation.

Refresher Course in Physical Therapy.—Didactic and clinical lectures, round table conferences, clinics and technical demonstrations will make up a course in physical therapy to be given before the annual session of the American Congress of Physical Therapy in Chicago September 7-10. Fundamentals will be reviewed but emphasis will be laid on the newer developments, according to the *Archives of Physical Therapy*. Fellows of the congress will be admitted to the course for a fee of \$20; for others the tuition charge will be \$25. Further information may be obtained from the American Congress of Physical Therapy, 30 North Michigan Avenue, Chicago.

Fewer Automobile Fatalities.—According to the National Safety Council, in the first four months of 1938 there were 2,060 fewer traffic deaths than in the corresponding months of 1937, a 19 per cent reduction. The North Central states showed the greatest improvement with a drop of 25 per cent; the South Atlantic states had a reduction of 14 per cent, South Central states 10 per cent and Pacific Coast states 11 per cent. The Rocky Mountain states reported an increase of 13 per cent. Of forty-two states reporting for either three or four months of both this year and last, twenty-eight showed decreases or no change. Oregon led the list with a drop of 40 per cent. Michigan was second with 39 per cent.

Society News.—Dr. Louise C. Eisenhardt, New Haven, was elected president of the Harvey Cushing Society at its seventh annual meeting in Memphis, Tenn., April 21-23; Dr. Frank R. Teachenor, Kansas City, Mo., is vice president, and Dr. William J. German Jr., New Haven, secretary.—The Western Institute for Hospital Administrators will be held at Stanford University, Calif., August 8-19; the institute is sponsored by the American College of Hospital Administrators, the Association of Western Hospitals and the Association of California Hospitals, jointly with the university. Mornings will be devoted to lectures, afternoons to field trips to hospitals and evenings to panel discussions.

Men Chief Victims of Fatal Home Accidents.—A recent study of mortality among industrial policyholders of the Metropolitan Life Insurance Company revealed that fatal accidents in the home were one and one half times as frequent among men as among women in the range 15 to 64 years. Death records show that falls off roofs, ladders, porches and balconies were much more frequent among men, as were falls down stairs. Deaths from poisonous gas were three times as frequent among men. Illuminating gas was the lethal agency involved in three fifths of the deaths and automobile carbon monoxide gas in one fourth of the deaths among men. Firearms were the third

most important cause of mortality among men. Deaths involving the cleaning or careless handling of loaded guns caused 1.2 deaths per hundred thousand male policyholders but only 0.2 among women. Accidental burns, exclusive of those sustained in conflagrations, were the only type of home accident in which more women than men were injured fatally.

Changes in Status of Licensure.—The Oregon State Board of Medical Examiners reports the following:

Dr. Joseph A. Wonderlick, Salem, license revoked April 6 for unprofessional and unlawful conduct.

The Colorado State Board of Medical Examiners reports:

Dr. Taber A. Darling, Fort Lupton, license restored April 5.

The State Medical Board of Ohio took the following action at a meeting April 5:

Dr. William E. Leever, Cincinnati, license suspended one year for violation of the Harrison Narcotic Act.

Dr. Mounce E. Byrd, Burbank, license suspended on his conviction of criminal abortion, for the period of his incarceration.

The Board of Medical Examiners of Maryland, Baltimore, announced the following action:

Dr. Robert Xavier Giering, Baltimore, license revoked March 4 because he was twice convicted of practicing criminal abortion and of having been found guilty of using the mails to obtain money under false pretenses.

Dr. Allan Hamilton Uhler, Baltimore, license revoked March 4 on account of his having been convicted of the larceny of two microscopes and of having used the mails to defraud.

The Massachusetts Department of Registration in Medicine announces the following action:

Dr. Solomon Gobert, East Boston, Mass., license suspended for six months, March 17, for testimony in court.

CANADA

Society News.—Drs. Gordon Gordon-Taylor and John Beattie, both of London, England, addressed the Academy of Medicine of Toronto April 5 on "Injuries of the Abdomen" and "Neurogenic Factors in the Control of Gastric Motility, Secretion and Ulceration" respectively.—Dr. Philip A. Clyde Cousland, Victoria, addressed the Victoria Medical Society April 7 on allergy.

Rural Health Contest Winner.—The first rural health conservation contest in Canada, held during the past year by the Canadian Public Health Association in cooperation with the American Public Health Association, was won by the St. Jean-Iberville-Laprairie-Napierville health unit, St. Jean, Que. Dr. Jean H. Maynard is the health officer. The U. S. Chamber of Commerce sponsored the contest and funds were supplied by the W. K. Kellogg Foundation. A plaque was to be awarded to the winning unit at the annual meeting of the Canadian Public Health Association in Halifax June 20-22.

FOREIGN

Personal.—Dr. I. Snapper, professor of pharmacology and pathology in the University of Amsterdam and director of the clinic for internal medicine in the Wilhelmina Hospital since 1919, has been appointed professor of medicine at Peiping Union Medical College, Peiping, China.

The Lister Medal.—Dr. René Leriche, professor of clinical surgery, University of Strasbourg, will receive the Lister Medal for 1939 and will deliver the Lister Memorial Lecture in 1939, according to *Science*. This is the sixth occasion of the award, which is made by a committee representing the Royal Society, the Royal College of Surgeons of England, the Royal College of Surgeons in Ireland, and the universities of Edinburgh and Glasgow. The medal is given in recognition of distinguished contributions to surgical science.

Congress on Tropical Medicine and Malaria.—The third United International Congress of Tropical Medicine and Malaria will be held in Amsterdam September 24 to October 1 under the auspices of the Netherlands Society of Tropical Medicine. Dr. G. Gryn's is the general president and Dr. N. H. Swellengrebel the president of the malaria congress. The general secretary is Dr. Ch. W. F. Winckel, Institute of Tropical Hygiene, Mauritskade 57, Amsterdam O. The secretary of the committee for the United States is E. Harold Hinman, Ph.D., Wilson Dam, Ala.

Society News.—The International Federation for Documentation will hold its fourteenth International Conference on Documentation at Lady Margaret Hall, Oxford, England, September 21-26, under the presidency of Sir William Bragg.—The fourth annual Congress of Electroradiologists of the French Language will be held in Paris October 5-8. At the opening session Prof. Frederic Joliot-Curie will speak on "Neutrons and Artificial Radio-Elements; Biologic Application, Therapeutic Hypotheses." Information may be obtained from Dr. Delherm, president of the congress, 1 Rue Las Cases, Paris 7.

The Radiotherapy of Brain Tumors

At the Society of Radiotherapists, W. C. Northfield opened a discussion on benign brain tumor, which he said comprised not only encapsulated ones, such as meningioma and acoustic neurinoma, but certain slowly growing gliomas. On the other hand, the spongioblastoma and the medulloblastoma were intensely malignant, and with these hopeless tumors the neurosurgeon turned to the radiotherapist. Other tumors might be considered malignant because of their position in the brain though histologically fairly benign. These included diffuse astrocytoma of the pons, speech centers or basal ganglions. For such tumors surgical extirpation was not feasible. In the choice of case for radiotherapy there was the difficulty of being certain of the diagnosis. As a rule it was desirable to precede irradiation by an operation, to avoid the risk of leaving a benign tumor, to relieve the increased intracranial pressure and to secure a histologic diagnosis.

Robert McWhirter described his technic. The location and estimated area of the tumor were indicated by the neurosurgeon on roentgenograms of the skull in two planes, often on the ventriculograms. With this guide he made a chart of the portals of entry and the directions of the exposures. To prevent unpleasant reactions, the initial doses were much smaller than the subsequent ones. He was optimistic about the results of radiotherapy in ameliorating the general symptoms and improving the neurologic status. There was general agreement as to the radiosensitivity of such gliomas as medulloblastoma, spongioblastoma multiforme and certain types of astrocytoma. In a few cases inoperable meningioma had also proved responsive. In cases of pituitary adenoma headaches were relieved and vision and endocrine disturbances were improved. With acromegaly there was improvement even in the face, so that new dentures were necessary, and in the extremities, so that smaller shoes could be worn. A note of warning was sounded as to the susceptibility of healthy brain tissue to irradiation. In patients who eventually died, softening of the white matter had been found in areas of the brain in the line of treatment. Radiotherapy of brain tumors was less advanced than radiotherapy elsewhere, and the technic was in need of development.

Air Raid Precautions

In the House of Commons, the home secretary, Sir Samuel Hoare, said that we were getting near the half-way mark of the million volunteers for defense against air raids for which he appealed two months ago. First aid and antigas training had been given to 126,000 men and women, and in addition 11,000 physicians, 1,300 dentists and 22,000 nurses had passed through the air raids precautions course. He had already issued to the local authorities 300,000 gas masks for training. A survey has been made of the hospital accommodations of the country for dealing with casualties. It has been suggested that the casualties should be taken as quickly as possible outside the area of London attacks, as these might be so formidable that it would be difficult for the hospitals to carry on, and that casualty hospitals should be formed on the periphery of London and victims moved from them into the country. The government has formed a committee consisting of hospital experts, the director of medical services in the war office and the principal medical officer of the London County Council to give advice. Directions are being issued to the hospitals as to the precautions they should take against air raids. Plans for the evacuation of the population from London and par-

ticularly for the evacuation of children are being considered. Another danger from air attack is interference with our immense sea-borne food supply. Plans for diverting shipping from the harbors of the east coast to the less dangerous ones on the west coast have been drawn up. Another precaution, adopted for the first time in this country, is the purchase by the government of large supplies of food for storage, some of which have already been delivered. The supplies consist of three commodities which can be stored for a long time without deterioration—wheat, sugar and whale oil. The wheat will be stored, so far as possible, in ports on the west coast. Whale oil was selected as supplying one of our greatest necessities—fat. It is of all oils the easiest to store and will keep for years without deterioration. It is a basic component of margarin.

Austrian Medical Refugees

The spread of political persecution from Germany to Austria has exercised the profession as to the prospects of their Austrian colleagues. Sigmund Freud has arrived in London from Vienna to take up residence with his son who lives here. He has been given a permanent permit by the government. He recently celebrated his eighty-second birthday, and his intention is to spend the remainder of his days here in study and research. He was met at the station by Dr. Ernest Jones, an eminent pupil, who drove him to his destination.

Dr. J. A. Ryle, professor of medicine in the University of Cambridge, has written to the medical press on assistance to Austrian medical students. A letter has been circulated to the deans of the medical schools of the British Isles pointing out that, while there is general agreement that there is no room for any great increase in the number of foreign physicians allowed to practice in this country, and that the best we can do is to offer asylum to individuals, the question of the medical student seems to be in a different category. He wonders whether we might not make some effort to provide opportunities for a limited number of Austrian medical students in the British Isles. The London Hospital has undertaken to take one student free of charge for the whole of his medical curriculum, on the understanding that his board and lodging can be privately provided. Professor Ryle suggests that each medical school should undertake the free education of one student on these conditions. By the time he is qualified, the student would be eligible for naturalization.

Present Status of Vaccination Against Tetanus

The question of whether antitetanus vaccination is effective has been the subject of a number of papers read at the Académie de chirurgie of Paris during the last two years. Prof. G. Ramon of the Pasteur Institute of Paris read a paper at the May 18 meeting of the Académie de chirurgie, in which the comparative efficacy of antitetanus serum and tetanus toxoid was reviewed. Although the ability of the serum to prevent this type of infection can no longer be questioned, there are limitations to its efficacy. The passive immunity following the injection of antitetanus serum takes place almost immediately but is of short duration. "Serum sickness" follows the injection of the serum. That death can follow an injection cannot be denied. Inability to work because of a comparatively insignificant injury may be prolonged as the result of serum sequelae. On the other hand, one must bear in mind that tetanus is not uncommon as a complication of an insignificant injury or of wounds with which its occurrence is not to be expected. It is evident that the routine use of the antitetanus serum presents a difficult problem, whereas vaccination with the tetanus toxoid does not expose the worker to any local or general reactions.

Tetanus toxoid does not immunize the subject until after a certain interval, but the immunity is permanent. The most important factor is that the toxoid increases the resistance of the patient and its administration is followed by a special ability of the organism to react when the injection is repeated. Rapid progress has been made recently in bestowing immunity on a large percentage of vaccinated persons. Transitory passive immunity follows repeated injections of the serum, but successive injections of the toxoid at more or less prolonged intervals create an ever increasing active immunity which is permanent. More than a million persons have been vaccinated with the toxoid in France, but not a single case of tetanus has been reported. The use of the toxoid in the prevention of tetanus deserves to be generally adopted. When the development of tetanus is to be feared, both the serum and the toxoid should be given. For children the injection of 3,000 units of serum is indicated, while for adults it is advisable to inject from 10,000 to 20,000 units. Fifteen minutes later 1 cc. of the toxoid should be injected, and in three weeks there should be a second injection, of 2 cc. of the toxoid. If possible a third and a fourth injection of the same dose of the toxoid should follow. If the injured person has previously been vaccinated, a single injection of 2 cc. of the toxoid suffices. If there is any doubt about a previous vaccination or the patient has lost a great deal of the antitoxin in the blood because of a severe hemorrhage, it is better to give also an injection of the serum. Vaccination by means of the toxoid calls for three injections and should be used as a matter of routine for all persons whose work exposes them to tetanus infection. For this reason the use of the toxoid is now obligatory for all soldiers. In the discussion, Dr. Louis Bazy stated that the principal arguments in favor of the toxoid are that it can be relied on to confer immunity in a far larger percentage of cases and that the immunity is not temporary, as is that produced by serum used preventively.

Prophylaxis Against Undulant Fever in France

At the May 17 meeting of the Académie de médecine of Paris a series of investigations on undulant fever were reported by Professor Lisbonne of Montpellier, in southwestern France. The research work was aided by the Rockefeller Foundation, which has established a center at Montpellier for this purpose. In 1924 the disease existed in only seventeen of the ninety departments of France. In 1938 this number has risen to seventy-six, the disease in all cases being confirmed bacteriologically. Infection of human beings by *Brucella abortus bovis* is not rare, and the center at Montpellier has found the disease in seventy cases from departments in northern, eastern and central France. In the South and Southwest, only *Brucella melitensis* has been observed in blood cultures. In three departments, in north-eastern, in eastern and in southeastern France, bovine brucellosis due to *Brucella melitensis* has been found. Direct infection of human beings ranks first as a mode of transmission, whereas infection by way of the alimentary tract ranks second. The lesser number of cases of the latter mode of transmission is the result of sterilization of contaminated milk, even in rural communities. Contact infection has been found to occur five times oftener than infection by ingestion of milk, cheese and other dairy products. General cleanliness, especially proper care of the hands, is less important in the prevention of infection due to *Brucella* than combating the disease at its source, that is, killing infected animals. The use of living vaccines for prophylactic purposes carries with it the danger of elimination of the bacteria and infection of healthy animals in contact with the vaccinated ones. Also there have been reports of infection of veterinary surgeons in handling living vaccines. Dead vaccines have not been found to be of any value. The ideal method would be to utilize nonvirulent bacteria. The Montpellier center, by combining injections of a nonvirulent

strain with injections of a glucidolipoid antigen of *Brucella melitensis*, has succeeded in successfully vaccinating guinea pigs in the majority of its experiments. In the discussion, Professor Lemierre of Paris stated that the cutaneous route of inoculation had been observed more frequently than any other at the contagious disease hospital here.

Action of Sulfanilamide on Experimental Pneumococcic Infections

At the May 24 meeting of the Académie de médecine of Paris, an extensive experimental study on the action of sulfanilamide was presented by Prof. Constantin Levaditi of the Pasteur Institute and his co-workers Vaisman and Krassnoff. In their earlier investigations the streptococcus was employed, and it was found that the action of sulfanilamide and similar preparations is proportional to the potential defensive powers of the organism. If this defense is lacking the therapeutic action of the drug will be inadequate. Complete sterilization can be expected only when both the index of the animal's resistance and the capsule formation—inhibiting and antitoxic properties of the newer drugs are at their maximum. In the present study the pneumococcus was selected because it possesses a tendency to capsule formation as a means of defense against the action of phagocytes and drugs which is much more marked than the streptococcus. Experiments were undertaken on mice. Three strains of pneumococci were chosen, a very virulent strain, a less virulent strain and a strain which was nonpathogenic and without a capsule. The drugs employed were 4-nitro-4'-acetylamino-diphenylsulfoxide and aurodetoxin, which according to the Gehes Codex is a compound of gold and a sulfur-rich keratin preparation of high molecular weight containing 12 per cent of gold (Vaisman). The cultures were injected intraperitoneally and the mice killed at varying intervals. From their first series of experiments, the authors concluded that preexisting encapsulation greatly increases the pathogenic action of the pneumococci. The capsule acts like an impermeable covering, which protects the pneumococci from being ingested by the phagocytes and favors multiplication of the pneumococci in the blood and tissues. The capsule-forming property of the pneumococcus plays the most important part in determining its virulence. In studying the mechanism of defense of the infected mice against nonvirulent and nonencapsulated pneumococci, it was found that specific defense of the blood serum against distinctly pathogenic and capsule-forming pneumococci, on the one hand, and phagocytosis, with its concomitant opsonic phenomena, on the other hand, have the principal roles. After this work had been done, the question was studied as to whether sulfanilamide and similar drugs have a bactericidal or bacteriostatic action.

The final conclusions of this investigation are as follows: The virulence of the pneumococcus is related more directly to the potential ability of this organism to form a capsule than to the phagocytic properties of the leukocytes. A strain of pneumococcus is pathogenic because it finds the materials in the body of the host which permit it to form a capsule. The various sulfur-containing newer drugs which are therapeutically active cause the pneumococcus to be more readily surrounded by the phagocytes, because these drugs act by creating an unfavorable medium for the formation of capsules by the pneumococci. This renders the bacteria an easy prey for the phagocytes. As a result of their previous studies of the action of sulfanilamide and similar drugs on the streptococcus and of their present investigation, Levaditi and his co-workers maintain that the drugs act (a) by being altered within the body, (b) by the ability of the body to regulate the rhythm of elimination of the drug, (c) by inhibiting multiplication of the bacteria, (d) by preventing capsule formation and (e) by aiding phagocytosis in destroying the bacteria temporarily or permanently.

New Developments in the Problems of Heredity

There has been of late a reduction in the number of new publications and regulations in the field of genetics. Nevertheless, several new and interesting pronouncements and decisions on the problem of heredity have been made. Genetic-biologic examination was employed as a means of proof in a recent case of the disputed paternity of a child. The Reichsgericht, as supreme German tribunal, in a recent opinion states that genetic examination can be of decisive importance in cases of this sort and should be employed in all doubtful cases. In this particular case the blood type test had been without result and a genetic test had been resorted to as a further source of evidence: "Since the test is undoubtedly a proper source of evidence; since it is particularly applicable in the present case; since the result of the test should decide the paternity of the child." On the other hand, according to one high juridical authority the genetic test should not be evaluated as an exact scientific source of evidence in favor of or against an alleged progenitor, and its accuracy is not comparable to that of the blood type test. The genetic test, however, may furnish data which vary in significance according to other circumstances of a given case. It may frequently be useful as a secondary, supplementary test. The genetic test is based on a similarity of certain hereditary external characteristics in father and child. Comparative studies are made, for example, of the hair of the head, eyebrows, eyelashes, palpebral fissures, color of eyes, nose, possible harelip or cleft palate, fissura oris, chin, ears, pattern of papillary ridges on the finger pads, palmar and plantar surfaces, color of skin, form of clavicle and form of vertebral column.

Dr. Gross, director of the bureau of racial eugenic policy of the Nazi party, recently discussed the problem of choice of a marriage partner by siblings of congenitally diseased persons. In many circles it is feared that the determination of hereditary disease imposes on the siblings of the affected person at least a moral obligation not to marry. This apprehension is baseless. Usually a hereditary disease will be present in one member of a group of siblings, whereas the others show no signs of the disorder and are never found to have transmitted a predisposition to their offspring. Sterilization of the diseased person should by no means be considered a reflection on the healthy siblings. The marriage of the siblings of the sick person should of course take place only after thoroughgoing medical examination and certification of genetic fitness.

Blood Typing as Means of Forensic Proof

The national government has just issued a new law with regard to cases of doubtful paternity, which represents a practical application of the Nazi concept of genetics and race. Of particular interest to the medical profession is the stipulation that in such cases the court may order both blood type and genetic tests. Heretofore judicial authority to order tests of this sort was open to question. The new law makes no pronouncement on the evaluation of the testimony of the child's mother; accordingly such testimony remains the first consideration. It follows then that these tests will be resorted to only if the mother's testimony is unsatisfactory; for example, if she is deemed untrustworthy. The blood test thus becomes a secondary consideration, the genetic test a tertiary. The courts are now provided with clear rules of legal procedure with regard to this problem.

Legitimate and Illegitimate Children

In the year 1936 about 1,210,000 babies were born in wedlock; namely, about 14,700 more than in 1935, whereas the number of those born out of wedlock increased by only 215. Of infants born in the year 1936, 7.8 per cent were illegitimate, as against

7.9 per cent in 1935. The proportion of infants born out of wedlock has tended to decrease constantly and substantially since 1930; this decline continued in 1936. During the years from 1926 to 1930, 12.3 per cent of newly born babies were illegitimate. The marked decrease in the proportion of illegitimate babies was at first due to the fact that women born during the war period of low birth rate, from 1915 to 1919, had reached the age levels at which the bearing of illegitimate children is most frequent. Since 1933 the further recession in the number of babies born out of wedlock has been due to the increase in number of marriages, the increased fertility of marriages and the institution of government subsidies to couples contemplating marriage. In 1936 an especially noteworthy increase was observed in the number of children born to those couples who had married before 1933 and whose fecundity had been markedly on the decrease because of unsettled general conditions prior to the latter year. Marriages contracted before 1933, especially those contracted in the years from 1920 to 1926, in 1936 still showed, after a duration of from ten to sixteen years, an increase in births of approximately 3 to 8 per cent over the figure for 1935, which figure represented an increase of from 30 to 40 per cent over that for 1933. In the year 1937 the number of babies born in wedlock amounted, according to preliminary figures, to about 1,270,000; namely, 314,000 more than in 1933. In the four years from 1934 to 1937 the number of legitimate children born within the German reich, including the Saar district, exceeded by 1,166,000 the number who would have been born had the extremely low rate of a year such as 1933 continued. Of the foregoing number 1,130,000 were born alive. This increase in births permits the assumption that not only among younger couples but among older couples as well the desire for children is stronger than in the past.

Dr. Guenter K. F. Schultze, senior physician of the Women's Hospital of Berlin University, has made a comparative clinical study of legitimate and illegitimate births. His material consisted of 15,000 married primiparas and 12,000 unmarried primiparas. It was observed that with regard to several puerperal complications the unmarried women fared better than the married women. Premature rupture of the fetal membranes and eclampsia were both much less frequent among the unmarried than among the married women. Surgical interventions were less frequently indicated for the unmarried mother. Rupture of the peritoneum, as well as transverse presentation, was, on the contrary, more common among the unmarried women. In the war years, when wives were separated from their husbands, premature rupture of the membranes was of about equal frequency in the two groups of women studied. This shows with all the clarity of an experiment that coitus during pregnancy was the most common cause of premature rupture of the membranes among women whose husbands were called away to war. Eclampsia was due to insufficient nutrition during pregnancy, as well as to overwork and excess of bodily movement. The conditions under which many unmarried women live during pregnancy may conduce to eclampsia. With regard to the incidence of surgical operations, the unmarried primiparas were substantially better off than the married women. Most noteworthy was the great difference with respect to the incidence of deliveries in which forceps had to be employed. Comparison of the corresponding age groups of married and of unmarried primiparas plainly showed the unmarried mothers to be more liable to rupture of the peritoneum. According to statistics that cover several decades, the number of stillborn illegitimate infants is about 1 to 2 per cent greater than the number of stillborn legitimate infants. The high proportion of stillbirths among unmarried women recorded in the national statistics is not based on an especially greater frequency of puerperal complications; the data show on the contrary that in many important respects the unmarried mothers fare better than the married. The difference lies in the obstetric treatment of the homeless unmarried mother. The proportion of premature births

is twice as great among unmarried women as among married women. Accordingly, premature birth is the most important aspect of the whole problem of illegitimacy from the obstetric point of view. In addition, the illegitimate child is likely to present characteristic developmental deficiencies which have begun during the intra-uterine life; the smaller neonatal weight of illegitimate infants is one manifestation of their debility. It is indicated on the basis of the statistical data that the unmarried gravida ought to receive home care during the final months of pregnancy and should be hospitalized during confinement.

Campaign Against Misuse of Alcohol

An agreement has recently been effected between the German wine growers and the national fuhrer of physicians on the following principles relative to the use and abuse of alcohol: The campaign against drunkenness is a part of German public health policy. There is no objection to the use of alcoholic beverages but only to intemperance. Broadly speaking, every adult citizen may indulge liberally, moderately or not at all, as he chooses. On the other hand, abstinence is demanded of children under the age of 17, women during pregnancy and lactation, persons whose health is endangered by alcohol and, finally, persons whose occupations entail a particularly great responsibility, drivers of motor vehicles, for example, both before and during driving. In addition, the production, marketing and wide distribution of new sweet wines are recommended.

ITALY

May 28, 1938.

National Congress on Tuberculosis

The fourth national congress on tuberculosis was held at Tripoli; Prof. Raffaele Paolucci of the University of Bologna presided. The first theme concerned the prophylaxis and treatment of tuberculosis. Professor Morelli of Rome, director of a large sanatorium, said that hospitalization of the tuberculous patient is an axiom in prophylaxis. Early diagnosis in a high percentage of cases is another necessity; it is above all the duty of the antituberculosis dispensaries, which, the author suggested, ought to be supplemented by mobile municipal clinics which would collaborate as much as possible with the outpatient clinics of the university and other hospitals.

At the second session the topic tuberculous bacillema was developed by Professor Daddi of the Istituto Forlanini of Rome. He emphasized the inadequacy of testing with Loewenstein's culture medium, which method, although much used, contains sources of error. He criticized the composition of the culture medium and the preparatory treatment of the blood (according to Rondoni and Petraghani the blood ought not necessarily to be deprived of hemoglobin). Loewenstein advises centrifugation of the blood in from 1,000 to 1,500 revolutions, whereas Besta has demonstrated the value of centrifugation of the blood at high velocity in short test tubes. Professor Daddi discussed the destiny of bacilli that are in the blood, as well as the formation of hematogenous metastases. The author cited Professor Morelli's concept of the filtering action of the lungs as an important factor in the arrest of bacterial emboli. Daddi's microscopic and bacteriologic investigations carried on in collaboration with Panà on cadavers of victims of phthisis showed that tubercle bacilli were present in the livers of 70 per cent and in the thoracic lymph nodes of 94 per cent. The spleens of 74 per cent were shown to be diseased by bacteriologic tests and the spleens of 30 per cent by microscopic tests. In many cases the bacillema had been unaccompanied by any clinical manifestations. Professors Mazzetti, Besta and Barchi objected to the method and conclusions of Loewenstein. Loewenstein considers bacillema a beneficent phenomenon even with those forms of pulmonary tuberculosis which are ordinarily considered of hematogenous origin and even after injections of epi-

nephrene. This is not at variance with the clinical and anatomic data which demonstrate the frequency of the hematic genesis of tuberculosis in the adult but only confirms the fact that it is difficult to detect the passage of the bacillus into the circulation. Such research is of scant clinical importance in the diagnosis and prognosis of pulmonary tuberculosis.

At the third session the theme prophylaxis against prenatal tuberculosis was discussed by Prof. Carlo Vercesi. In discussing the tuberculous gravida, he reiterated what he had advanced in previous writings; namely, that pregnancy does not of itself contain any constant factors through which tuberculosis may be reactivated or aggravated. On the other hand, during the period of gestation all modern procedures of tuberculosis therapy can be advantageously employed. The obstetric care of the tuberculous gravida should be conservative; rarely is interruption of pregnancy indicated. The foregoing opinion is in accordance with that of the more authoritative obstetric clinicians both in Italy and abroad. With regard to the intra-uterine processes, studies have tended to minimize the importance of contagion from passage of filtrable virus. Although the development of the majority of babies of tuberculous mothers is below normal, the incidence of specific lesions is no greater than among other infants, provided they are immediately removed from contact with the tuberculous mother and other infected persons. Among the safeguards recommended for the tuberculous gravida the author urged first, hospitalization in an institution equipped to care for both women in childbirth and tuberculous patients. He urged the establishment of obstetric units in the larger sanatoriums and of special units for the care of tuberculous patients in other hospitals. Such combinations of facilities would make possible better collaboration between obstetrician and phthisiologist; this in turn would lead to greater availability of modern therapeutic methods, including collapse therapy. Prof. Rocco Jemma called the attention of the congress to the problem of tuberculosis in the nursing. The agencies for the treatment of tuberculosis in childhood should be welded into one strongly organized front. He mentioned the little recognized fact that servants and elderly relatives may be important carriers of infection. He attested the value of antituberculous vaccination of children with Maragliano's serum or Petraghani's tuberculin, supplemented in some cases by administration of BCG vaccine. Surgeon Major Professor de Paoli and Prof. Alberto Ciotola, director of the Colonial Hospital, Tripoli, reported on the extent of tuberculosis in Tripolitania. The diffusion of tuberculosis in North Africa corresponds closely to the urbanization of the population. It was the opinion of the discussers that present data on tuberculosis in the colonies are inadequate. It was accordingly proposed that the next national antituberculosis congress take up as a principal topic tuberculosis in the African colonies.

Plastic Surgery

Before the Società di chirurgia plastica ed estetica, Professor Manna discounted the idea that plastic surgery and cosmetic surgery are two independent disciplines, the first appertaining to general surgery and the second being employed essentially by the luxury class. Manna believes that since plastics attempts the reconstruction of mutilated and deformed tissues, cosmetic surgery ought to be considered a special branch of plastics, having as its purpose the restoration of the cosmetic function of damaged tissues. Its objectives are then both social and humanitarian. The application of cosmetic surgery is difficult; often from fifteen to twenty interventions have to be performed on the same patient to effect gradual adaptation of the tissues to the new circumstances of topography, circulation and consistency. As to the legal responsibility of the surgeon when a cosmetic operation falls short of its objective, the author maintains that this problem can be solved by application of the forensic principles already applied to general surgery.

Malaria Research

The Istituto Italiano di malariologia sent out to Ethiopia a medical research mission composed of Professors Lega and Raffaele, Dr. Canalis and a preparator. After four months in the field the commission reported that malaria is prevalent in Ethiopia, even on the lofty plateau regions 2,000 meters above sea level. The benign tertian type predominates; it occurs in epidemics which last the greater part of a year. In the lowlands malaria is endemic but less so than in the intermediate highlands. In the lowlands *Plasmodium vivax* is more common than *Plasmodium falciparum* as the causal agent. Quartan malaria is rare; cases in which the disease was caused by *Plasmodium ovale* were not observed. A new species of *Plasmodium falciparum* was frequently observed; it is characterized by definite peculiarities, both morphologic (larger trophozoites and shorter and wider gametocytes) and biologic (precocious exflagellation of the male gametocytes, scant pathogenicity in *Anopheles*). Lega and Raffaele have named this well differentiated species "aethiopica." Anophelism is extremely common even at altitudes above 2,000 meters; e. g., at Addis Abeba (2,640 meters above sea level). Thirteen species of *Anopheles* were observed, among them *Anopheles d'thali* and *Anopheles turkhudi*, previously believed restricted to the eastern Mediterranean region.

SWITZERLAND

Case of Spontaneous Poliomyelitis in an Animal

The literature contains no report of spontaneous acute anterior poliomyelitis in an animal, and experimental inoculation has thus far succeeded only in apes. Therefore a case reported by Dr. E. Frauchiger at Langenthal, canton of Berne, is of the utmost importance. A heifer aged 1½ years, of healthy stock, was observed one morning to present a slight dragging of the left hind leg; by evening both hind legs were involved. On the following morning she was no longer able to stand; the fore legs were still mobile, whereas the hind legs had become completely limp and paralyzed. On the fourth day after manifestation of the initial symptoms all four extremities were completely paralyzed, the respiration was labored and the animal became so distended and restless that it had to be destroyed. No similar sickness had been observed previously among the live stock of this particular farm, nor had any cases of poliomyelitis been reported among the children of the neighborhood. As usual in cases of poliomyelitis, the necropsy revealed no specific macroscopic changes except hyperemia. Microscopic observations, on the contrary, were extremely characteristic, most notably in the lumbosacral portions of the spinal cord. The changes were identical with those that have been recognized in human subjects, and particularly with the changes described by Dr. Walthard of the Berne Institute of Pathology during the epidemic of 1937. In fact, it was Walthard who established the similarity by comparative microscopic study of the tissues. The course and symptoms of the heifer's illness corresponded with the clinical picture of reported fatal cases of acute ascending paralysis in man. It was recognized that more cases of the acute ascending form were observed during the poliomyelitis epidemic of 1937 than during previous epidemics. The analogy of the clinical picture, however, tells nothing with regard to a similarity or dissimilarity of the causative agent. Dr. Frauchiger says that this, the first case of spontaneous poliomyelitis in an animal to be recognized, permits the anticipation of other instances in the future. Possible cases should be reported while the animal is yet alive, so that experimental immunologic studies of the brain and of the spinal cord can be made. Transmission of the infection from animal to man can no longer be rejected. Research on the inoculation of cattle should now be renewed. Descriptions in the literature of minor epidemics of poliomye-

litis following ingestion of milk from a sick cow may be viewed in a new light. It may perhaps be useful to produce a heterologous immunizing serum from cattle, which would supplement Pettit's serum obtained from the horse. The virus of poliomyelitis may be modified in the direction of a virus fixe, in the pasteurian sense, and this principle as utilized in the study of rabies may be applied to poliomyelitis.

Epidemic of Poliomyelitis in a Regiment

The *Schweizerische medizinische Wochenschrift* recently published a report by Dr. Hans Stahel, regimental surgeon, on a singular epidemic of poliomyelitis. Within the short space of twelve days in July 1937, six of 930 soldiers came down with meningeal and myelitic symptoms, sixteen with purely meningeal manifestations and 108 with more or less marked catarrhal disturbances. Correct diagnosis was made almost immediately in the first case. The necessary procedures, including instructions to the men, were instituted. Virtually on the same day six other men reported sick. The clinical pictures were strikingly similar; there was obvious involvement of the nervous system. During the next few days the epidemic continued to spread, but now a surprising change in the character of the disorder became recognizable. The number of cases of neurologic involvement abruptly declined, whereas catarrh of the upper part of the respiratory tract and severer generalized symptoms came to the fore. Differential diagnosis between poliomyelitis and influenza became uncommonly difficult. Prominent in the clinical syndrome of poliomyelitis were malaise that had begun one or two days previously, persistent headache, sense of tension, stiffness of neck and back and localized myalgia. In most cases recovery took place without permanent sequels within a maximum of five weeks. The 108 cases of catarrhal disturbances (83 per cent of all observed cases) could be classified apparently as cases of abortive poliomyelitis. The opinion that the milder forms represented poliomyelitis rather than epidemic influenza was substantiated among other things by the fact that, although 5,000 other troops were stationed in the vicinity, no untoward rise in incidence of "army catarrh" took place. Moreover, patients with catarrhal poliomyelitis present certain peculiar characteristics: profuse perspiration, localized myalgias that did not shift from time to time (as happens in influenza) and a diphasic fever curve.

In contrast to other epidemiologic records, a morbidity of 14 per cent was reported; namely, a proportion 100 times greater than had ever been reported in the literature of poliomyelitis epidemics. Stahel believes that from his thoroughgoing epidemiologic studies of this highly homogeneous group a better insight into the true circumstances of epidemic poliomyelitis has been gained than would have been possible among the civilian population. Apparently one ought to regard involvement of the nervous system as a complication of the milder forms. Acute anterior poliomyelitis in all likelihood is not a distinct entity but a less common, more malignant form of the disease. From the standpoint of epidemiology the abortive forms of poliomyelitis must enlist greater interest. More energetic efforts should be made to quarantine all possible carriers of contagion; namely, all persons with catarrhal disturbances. Living quarters and other premises frequented by suspected carriers also should be placed under quarantine. In congested areas such measures cannot of course be very promising. During the epidemic in question, although the stricken regiment had certainly been in contact with the neighboring civil population, not a single authentic case of poliomyelitis could be determined among the latter.

The Nursing of Infants

A distinguished physician, Frau Dr. Imboden-Kaiser, has published in the *Schweizerische medizinische Wochenschrift* some data on the feeding of nurslings, a problem with which she has been concerned for decades. In the city of St. Gall thirty years and more ago, the mortality for nurslings was quite high;

in 1904 it was still 18 per cent. In the year 1910, of 2,000 babies in the first year of life, 13 per cent of those who had not been suckled and 6 per cent of those who had been suckled died. Dr. Imboden at that time considered these facts proof that Swiss women were tending to lose the habit of breast feeding. She campaigned for the longest possible period of lactation, with the result that at St. Gall the number of breast-fed infants increased (from 53.4 per cent of all babies in 1904 to 89.5 per cent in 1932), whereas the mortality for nurslings declined (from 18.2 per cent in 1904 to 2.9 per cent in 1932). Other influences were present, but the foregoing figures offer certain proof that the increase in natural breast feeding was the principal factor in the decline of the mortality. In 1914 the federal government established lactation prizes for mothers who suckled a baby for ten weeks. This measure gave a powerful impetus nationally to the breast feeding of infants. From 1918 an almost uninterrupted rise in the Swiss curve of lactation took place; the percentage rose from 46 in that year to 60 in 1931. A slow regression has since occurred; the rate in 1936 was 56.2 per cent. Further comprehensive surveys have disclosed that well conducted infant welfare agencies can be of tremendous assistance in raising the rate. In the year 1936, for example, of about 600 nurslings supervised by Dr. Imboden's own service, 98 per cent were breast fed. The collaboration of the lying-in hospitals is important. No "artificial" feeding of infants should be permitted. Difficulties of lactation or a true deficiency of secretion should be combated with the breast pump as well as with donations of pumped breast milk. A propaganda campaign should be carried on among lying-in women. An important influence inimical to breast feeding is the lavish advertising of the purveyors of baby foods.

Appointment to the Chair of Surgery at Berne

A succession of distinguished incumbents has held the chair of surgery at Berne University. It was long occupied by Professor Kocher, who in 1909 was awarded the Nobel prize for his research on the thyroid. Prof. Fritz de Quervain, who succeeded Kocher on the latter's death in 1917, has now reached the age of 70 and relinquished his post in compliance with the retirement rules. De Quervain, himself a pupil of Kocher, has carried on the development of the famous school of surgery. In 1909 he was called to the chair of surgery at Basel, but he returned to Berne as ordinarius in 1918. With his retirement medicine loses the active services of one of the greatest of Swiss surgeons. De Quervain's contributions to clinical knowledge of the disorders of the thyroid are of the first importance; his book on goiter, for example, has appeared in several languages. His principal literary contribution was his "Clinical Surgical Diagnosis," which has been translated into five languages and is considered a classic of surgery. As a personality de Quervain is highly respected and revered. He is an excellent lecturer whose utterances always seem well considered and pertinent. Prof. Hermann Matti has been appointed to succeed de Quervain. Matti also is a pupil of Kocher and a surgeon of distinction. He is 58 years old and has been director of the surgical section of a Berne hospital. He has done important work on the surgery of gastric carcinoma, on the physiology and pathology of the thymus and in other fields, but he is best known through his two volume work on fractures and their treatment.

Prof. Otto Naegeli is Dead

Prof. Otto Naegeli, for many years ordinarius in internal medicine at Zurich, died March 11, aged 67. He had relinquished his professional chair on account of serious illness two years ago. His passing removes a great personality and a renowned internist. After he had served as ordinarius at Tübingen, Germany, he returned in 1908 to Zurich University, where he had won his first academic laurels, to become professor of internal medicine and director of the medical clinic. Naegeli was the son of a physician whose reputation was inter-

national. Of his many innovations only a few can be mentioned here: the discovery of Naegeli's blood syndrome of pernicious anemia, recognition of the significance of study of the bone marrow, emphasis on the dynamic theory of the hematic processes, evaluation of the leukemias, description of the "hiatus leucaemicus," recognition of the constitutional aspect of chlorosis and discovery of the genetic factor in hemolytic icterus. Shortly before his death Naegeli completed a treatise on "Differential Diagnosis in Internal Medicine," which reflects his mastery of the field. His classic textbook "Blood Diseases and Blood Diagnosis" has appeared in five editions. The esteem in which Naegeli was held, in Switzerland and abroad, found expression in many different ways.

AUSTRALIA

(From Our Regular Correspondent)

May 10, 1938.

National Health and Pensions Insurance for Australia

More than one in every four persons in Australia will be brought into compulsory insurance by the national health and pensions insurance bill, now passing its second reading in the federal parliament. More than half the population, including wives and children, is affected indirectly. It is proposed to make the legislation operative from January 1939. The scheme provides guaranteed benefits for sickness and disablement, together with old age pensions for insured persons and pensions and allowances for their widows and orphans. It is based on compulsory contributions and will apply to all persons over 14 years of age under contract of service to do manual work, whatever the rate of pay, and to those doing nonmanual work provided their salary is not more than £365 per year. The ordinary total weekly contribution at the inception of the scheme will be 3 s. per week for an employed man and 2 s. for an employed woman, the contributions being shared equally by employer and employee. Contributions will be collected through the postoffice by the sale of insurance stamps; they will be supplemented by a substantial annual grant from the commonwealth treasury. The benefits provided are medical attendance and treatment; weekly cash payments during sickness and disablement; superannuation pensions for insured persons, life pensions for their widows and pensions for their orphans up to the age of 15 years; allowance for the dependent children under 15 of persons receiving pensions or sickness or disablement benefits. The medical benefit will be a general practitioner service. A complete range of drugs and medicines and certain medical and surgical appliances will be supplied on the prescription of the medical practitioner. The British Medical Association has agreed to a capitation fee of 11 s. per head per year for each insured person. To meet the special difficulties of country doctors, additional payments from the national insurance fund will be paid for mileage involved. One of the difficulties in Australia is to provide adequate medical service for areas with a sparse population and long distances between patients. The ultimate scheme will bring in bush hospitals and "flying" doctors.

All insured persons may select their own doctor and pharmacist. A weakness of the scheme lies in the restriction of medical benefits to the insured person. Administration of the scheme will be in the hands of approved societies. Friendly societies, trade unions, mutual life assurance societies and other existing provident and welfare organizations may register as approved societies so long as they conform to the requirements laid down in the bill. No society will be permitted to reject an applicant for admission on the ground of age, and an insured person will be entitled to sickness benefits when certified to be incapable of work up to the age at which the old age pension is payable. Continuity of insurance and benefits during prolonged sickness is provided for. The present

plan covers only employed persons. Small farmers, storekeepers and business men are not covered by the provisions of the bill, and it is considered that a careful exploration should be made of the subject of voluntary insurance of the self-employed person, with a view to extending to him, if at all possible, the benefits of the scheme.

Library Service for Surgeons

This year the Council of the Royal Australasian College of Surgeons will receive the endowment provided by the late Gordon Craig, a foundation fellow of the college, who was always anxious that one of its main functions should be the teaching of surgery in its highest forms, teaching which concerns not only the education of medical men who wish to become competent surgeons but the continued education of fellows. The council feels that there can be no better method of educating its fellows than by making available to them, by a library service in their widely separated homes throughout Australia and New Zealand, all the resources of modern surgical literature. The present library, attached to the college building in Melbourne, is fully stocked with current literature and contains a number of recent surgical works; these, with other books, reprints and periodicals, which will be added, will form the basis for the Gordon Craig Memorial Library. The council will design the library service so that it will come within the reach of every fellow of the college. As each research into literature on a special subject is made at the instance of a fellow, it will be filed for the benefit of future investigators of the same subject. The fellows will be kept in touch with incoming literature in several ways. The Council hopes thus to build up eventually the best reference library of surgical literature in the Southern hemisphere.

Limitation of Pharmacies

A feature of pharmaceutical legislation which is new to both Britain and America is now in operation in New Zealand. Under the pharmacy reorganization plan, provision is made for the ultimate limitation of pharmacies on a basis of population. Licenses will be issued on a definite system, and, as part of the new order, a compulsory uniform scale of charges for dispensed medicines will be brought into operation. Under the plan, pharmacies will be redistributed as far as possible, so as to give the public more adequate service.

Marriages

ERNEST LANGSDORFF NOONE, Drexel Hill, Pa., to Miss Joyce Mary Toulmin of Broughton, England, May 12.

EDWIN F. BAKER, Ashton, Ill., to Miss Mildred Louise Short of Chicago, at Tipton, Iowa, April 14.

EDWARD O. BAUER, Middletown, Ohio, to Miss Juanita Rae DeArmand of Rockford, in March.

GUSTAVUS CLAGGET BIRD JR., to Miss Mildred Alice Spotts, both of Philadelphia, April 2.

JAMES C. KELTON, Lascassas, Tenn., to Mrs. Anna Davis King of Nashville, March 2.

JAMES DUBLEY WHITEHEAD to Miss Maria Weaver, both of Lake City, S. C., in April.

RAYMOND ROBINSON CALLAWAY to Miss Sue Clay, both of Birmingham, Ala., June 9.

ELIAS S. FREY to Miss Elizabeth Belle Ferguson, both of Louisville, Ky., April 7.

EDWARD B. PITTS, Fairfield, Ala., to Miss Katherine Shaefer at Opelika, in April.

IRVING GREENE to Miss Terese Claire Schwarz, both of New York, April 30.

EDWIN M. STEVENSON to Miss Mabel Dean, both of Memphis, Tenn., April 5.

PAUL S. HANSEN to Miss Elizabeth Coit, both of Chicago, March 26.

Deaths

Lewis Webb Crigler @ New York; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staffs of the New Rochelle (N. Y.) Hospital, Manhattan Eye, Ear and Throat Hospital, Horton Memorial Hospital, Middletown and the Peekskill (N. Y.) Hospital; aged 61; died, April 30, of heart disease.

Charles A. Bolich, Wadsworth, Ohio; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1897; member of the Ohio State Medical Association; veteran of the Spanish-American War; past president of the Medina County Medical Society; on the staff of the Wadsworth Municipal Hospital; aged 65; died, April 23, in the People's Hospital, Akron, of chronic myocarditis.

Lewis Thomas Rhoads, Lincoln, Ill.; Hahnemann Medical College and Hospital, Chicago, 1902; member of the Illinois State Medical Society; past president of the Logan County Medical Society; served during the World War; formerly member of the school board; on the staffs of the Evangelical Deaconess Hospital and St. Clara's Hospital; aged 63; died, April 13, of chronic myocarditis.

Frank Lauman Watkins @ Great Falls, Mont.; Ohio Medical University, Columbus, 1901; city and county health officer; formerly director of health education in the public schools of Tulsa, Okla.; at one time in charge of the Ohio Bureau of Vital Statistics and was affiliated with the Mississippi and Florida state boards of health; aged 58; died, April 8, in the Deaconess Hospital of lobar pneumonia.

John Mason Williams, Paris, Ky.; Louisville (Ky.) Medical College, 1893; member of the Kentucky State Medical Association; past president of the Bourbon County Medical Society; veteran of the Spanish-American War; formerly member of the city board of health; on the staff of the W. W. Massie Memorial Hospital; aged 67; died, March 12, in Lexington of coronary sclerosis.

Willard Curtis Proud @ St. Joseph, Mo.; University Medical College of Kansas City, 1896; Rush Medical College, Chicago, 1900; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staff of the Missouri Methodist Hospital; aged 64; died, April 29, of carcinoma of the colon.

Daniel Robins Saunders, Franklin, Ind.; Southwestern Homeopathic Medical College and Hospital, Louisville, Ky., 1897; member of the Indiana State Medical Association; past president and secretary of the Johnson County Medical Society; city and county health officer; aged 85; died, April 5, in the Methodist Hospital, Indianapolis.

Vance Rawson @ Chicago; Hahnemann Medical College and Hospital, Chicago, 1901; formerly member of the school board in Danville, Ky.; served during the World War; at one time professor of internal medicine at his alma mater; on the staff of the Chicago Memorial Hospital; aged 61; died, April 19, of coronary thrombosis.

Theodore B. Templin, Gary, Ind.; Jefferson Medical College of Philadelphia, 1904; member of the Indiana State Medical Association; fellow of the American College of Surgeons; on the staffs of the Methodist Episcopal and St. Mary's Mercy hospitals; aged 58; died, April 26, of cerebral hemorrhage.

Harry Herbert Satchwell @ Newark, N. J.; University and Bellevue Hospital Medical College, New York, 1904; member and past president of the state board of medical examiners; on the staffs of the Presbyterian and St. Michael's hospitals; aged 54; died, April 6, of hypertension and nephrosclerosis.

William B. Treadwell, Lufkin, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1883; member of the State Medical Association of Texas; formerly on the staff of the Angelina County Hospital; aged 81; died, March 5, of arteriosclerotic heart disease.

Albert R. Wilson, Greensboro, N. C.; Jefferson Medical College of Philadelphia, 1882; member of the Medical Society of the State of North Carolina; past president of the Guilford County Medical Society; aged 78; died, April 22, of pernicious anemia and heart disease.

Orlando S. Ritch, Brooklyn; New York Homeopathic Medical College, 1878; on the staffs of the Cumberland, Prospect Heights and Infants' hospitals; fellow of the American College of Surgeons; member of the board of trustees at his alma mater; aged 70; died, April 12.

John Price Brown, Toronto, Ont., Canada; M.B., University of Toronto Faculty of Medicine, 1868, and M.D., in 1869;

L.R.C.P., Edinburgh, Scotland, 1883; member of the American Laryngological, Rhinological and Otolological Society; aged 93; died, April 3.

Charles Atwood Menefee ☉ Covington, Ky.; Kentucky School of Medicine, Louisville, 1898; president of the Campbell-Kenton Counties Medical Society; on the staff of St. Elizabeth's Hospital; aged 69; died suddenly, April 18, of cerebral hemorrhage and hypertensive cardiovascular disease.

Ralston Lattimore, Savannah, Ga.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1893; member of the Medical Association of Georgia; fellow of the American College of Physicians; aged 67; died, April 20, of arteriosclerosis and pneumonia.

Howard Patrick Doles, Mooringsport, La.; Tulane University of Louisiana Medical Department, New Orleans, 1912; served during the World War; aged 51; died, April 5, in the Highland Sanitarium, Shreveport, of general peritonitis and ruptured duodenal ulcer.

Charles Henry Field, Bradenton, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1891; member of the Florida Medical Association; formerly member of the state legislature; aged 68; died, April 18, of cerebral arteriosclerosis and coronary occlusion.

Henning F. B. Wiese ☉ Minneapolis; Kongelige Frederiks Universitet Medisinske Fakultet, Oslo, Norway, 1915; fellow of the American College of Surgeons; on the staffs of the Asbury and Fairview hospitals; aged 48; died, April 29, of carcinoma of the stomach.

William Lee Gannaway, Abingdon, Va.; University of the South Medical Department, Sewanee, Tenn., 1900; member of the Medical Society of Virginia; aged 61; died, April 17, in the George Ben Johnston Memorial Hospital of coronary occlusion.

Henry Wilson Ring, New Haven, Conn.; Medical School of Maine, Portland, 1887; member of the American Ophthalmological Society and American Otolological Society; aged 81; died, April 3, of myocarditis, nephritis and cerebral hemorrhage.

Jasper N. Walker, Bastian, Va.; University of Virginia Department of Medicine, Charlottesville, 1898; formerly member of the state legislature, and secretary of the board of health of Bland; aged 71; died, April 8, of cerebral hemorrhage.

John William Augustus Sanders, Lugoff, S. C.; Medical College of Virginia, Richmond, 1904; member of the South Carolina Medical Association; aged 61; died, April 22, in the Camden (S. C.) Hospital of acute coronary occlusion.

William Dacre Walker ☉ Andover, Mass.; Tufts College Medical School, Boston, 1905; for many years school physician, and member of the school committee; member of the New England Roentgen Ray Society; aged 60; died, April 12.

Sidney Le Grand Williams, Shreveport, La.; Tulane University of Louisiana Medical Department, New Orleans, 1899; at one time superintendent of the Charity Hospital; on the staff of the Highland Sanitarium; aged 61; died, April 9.

Brickhouse Wilson ☉ Independence, Mo.; Emory University School of Medicine, Atlanta, 1917; served during the World War; on the staff of the Independence Sanitarium and Hospital; aged 44; died, April 4, of coronary heart disease.

Wilton Allen Woodburn ☉ Pittsburgh; Jefferson Medical College of Philadelphia, 1902; on the staff of the Columbia Hospital, Wilkinsburg; aged 57; died, March 20, in the Columbia Hospital of carcinoma of the cecum.

Robert Jones Hunter, Greensburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1906; member of the Medical Society of the State of Pennsylvania; served during the World War; aged 55; died, March 30.

Walter Lawrence Blomgren ☉ Chicago; Bennett College of Eclectic Medicine and Surgery, Chicago, 1915; served during the World War; aged 44; died, April 20, in the Edgewater Hospital of staphylococcal septicemia.

Joseph A. Anderson, Antreville, S. C.; University of Maryland School of Medicine, Baltimore, 1886; member of the South Carolina Medical Association; aged 76; died, April 10, in the Anderson (S. C.) County Hospital.

Joseph Bishop Wolfe Jr., Coeburn, Va.; Louisville (Ky.) Medical College, 1891; member of the Medical Society of Virginia; aged 69; part owner of the Coeburn Hospital, where he died, April 7, of heart disease.

Harry Hall Wilson, Black Mountain, N. C.; New York University Medical College, New York, 1897; served during the World War; aged 64; died, April 4, in the Halifax District Hospital, Daytona Beach, Fla.

Lester Lawrence Anderson, Stoneville, N. C.; Medical College of Virginia, Richmond, 1927; member of the Medical Society of the State of North Carolina; aged 35; died, April 18, of coronary thrombosis.

Frank Raymond Sandt, Paterson, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; on the staff of the Paterson General Hospital; aged 61; died, April 5, of coronary occlusion.

David H. Montgomery, Union, S. C.; University of Tennessee Medical Department, Nashville, 1895; member of the South Carolina Medical Association; aged 69; died, April 22, of intestinal obstruction.

Benjamin Nadel, Brooklyn; Long Island College Hospital, Brooklyn, 1912; formerly on the staffs of the Beth Israel and Jewish Maternity hospitals, New York; aged 52; died, April 3, of coronary thrombosis.

William Hamilton Cantwell, Shawano, Wis.; Rush Medical College, Chicago, 1887; formerly postmaster and health commissioner; aged 79; died, April 30, of arteriosclerosis and coronary occlusion.

John Joseph Pietrzak, Detroit; Wayne University College of Medicine, Detroit, 1935; aged 30; died, April 6, at the Herman Kiefer Hospital of pulmonary tuberculosis and spontaneous pneumothorax.

William Alex. Wovschin, New York; University and Bellevue Hospital Medical College, New York, 1912; served during the World War; aged 55; died, April 15, in the Montefiore Hospital.

William C. Wimberly, Fort Gaines, Ga.; Kentucky School of Medicine, Louisville, 1889; member of the Medical Association of Georgia; aged 75; died, March 1, of bronchitis and hypertension.

William A. James, Chester, Ill.; St. Louis Medical College, 1881; member of the Illinois State Medical Society; aged 83; died, April 15, in St. Clement's Hospital, Red Bud, of intestinal obstruction.

Hugh Vincent Cunningham ☉ Johnstown, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1928; president of the staff of the Mercy Hospital; aged 36; died, March 27.

Clyde Crawford Hardison ☉ Iron City, Tenn.; University of Nashville Medical Department, 1910; served during the World War; aged 49; died, April 14, in the Coffee Memorial Hospital, Florence.

Harmon P. McKnight, Milford, Neb.; College of Physicians and Surgeons, Keokuk, Iowa, 1890; aged 80; died, April 29, in the Nebraska Soldiers and Sailors Home of arteriosclerosis.

William G. Blackwell, McCormick, S. C.; University of the South Medical Department, Sewanee, Tenn., 1898; aged 60; died, April 10, of a severed jugular vein in a hospital at Greenwood.

Joseph New Campbell, Stamford, Neb.; Lincoln Medical College of Cotner University, 1902; member of the Nebraska State Medical Association; aged 58; died, April 12, of pneumonia.

Joseph George Beaty ☉ Chilhowee, Mo.; Missouri Medical College, St. Louis, 1893; president of the Johnson County Medical Society; aged 71; died, March 24, of coronary thrombosis.

Jennie Newman Norris, Atlanta, Ga.; Woman's Medical College of Georgia and Training School for Nurses, Atlanta, 1891; aged 76; died, April 5, in the Grady Hospital of carcinoma.

Clarence Galleher Rea, Muncie, Ind.; Jefferson Medical College of Philadelphia, 1904; formerly city health officer; aged 58; died, April 9, at Rochester, Minn., of carcinoma of the colon.

Mary Fisher, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1889; member of the Medical Society of the State of Pennsylvania; aged 85; died, March 30.

Nathan H. Bickley, Stamford, Texas; Memphis (Tenn.) Hospital Medical College, 1892; member of the State Medical Association of Texas; health officer; aged 73; died, April 17.

Dallas McKeever Murphy ☉ Bethesda, Ohio; Starling Medical College, Columbus, 1898; past president of the Belmont County Medical Society; aged 64; was found dead, April 4.

Edward W. Greenlee, Kansas City, Kan.; College of Physicians and Surgeons, Medical Department Kansas City University, 1899; aged 74; died, April 17, of chronic osteomyelitis.

Lorin Anson Walker, Owego, N. Y.; University of the City of New York Medical Department, 1883; aged 79; died, March 24, of rheumatoid arthritis and chronic myocarditis.

Louis F. Donaghue, Mahanoy Plane, Pa.; Medico-Chirurgical College of Philadelphia, 1898; formerly county coroner; aged 62; died, March 20, of bronchopneumonia.

Clarence Eugene Brinckerhoff, Miami, Fla.; College of Physicians and Surgeons of Chicago, 1885; aged 78; died, April 19, of chronic myocarditis, arteriosclerosis and nephritis.

Luther P. Youmans, Swainsboro, Ga.; University of Georgia Medical Department, Augusta, 1892; aged 71; died, April 8, in a hospital at Savannah of influenza and myocarditis.

John David Nicodemus, Walkersville, Md.; Jefferson Medical College of Philadelphia, 1879; aged 83; died in April of cardiovascular renal disease and bronchopneumonia.

Samuel French, Plymouth, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1893; aged 68; died, March 13, in Kingston of cerebral hemorrhage.

Needham Kahn Moody, Memphis, Tenn.; University of Tennessee College of Medicine, Memphis, 1912; aged 49; died, April 18, in the Gartly-Ramsay Hospital of pneumonia.

Lewis Martin Tinker Ⓢ Frankfort, Ohio; Bellevue Hospital Medical College, New York, 1894; served during the World War; aged 68; died, March 9, of coronary thrombosis.

Cook Bar Young, Kansas City, Mo.; Canton University Medical Department, Canton, China, 1889; aged 70; died, March 13, of chronic myocarditis and hypertension.

Richard Baxter Rand, North Abington, Mass.; Dartmouth Medical School, Hanover, N. H., 1893; member of the Massachusetts Medical Society; aged 70; died, April 18.

John A. Rhodes, Crawfordville, Ga.; University of Georgia Medical Department, Augusta, 1887; member of the Medical Association of Georgia; aged 74; died, April 9.

George Washington Chabot Ⓢ Peebles, Ohio; Miami Medical College, Cincinnati, 1886; aged 75; died, April 19, of coronary thrombosis following prostatectomy.

Perry M. Lewis, Orlando, Fla.; Atlanta Medical College, 1915; member of the Florida Medical Association; aged 46; died, April 30, of a self-inflicted bullet wound.

Orion Kemper Thomson, Chicago; Miami Medical College, Cincinnati, 1889; aged 71; died, March 11, of chronic nephritis, prostatitis and arteriosclerosis.

James Elijah Neely, Kansas City, Mo.; Barnes Medical College, St. Louis, 1904; member of the Missouri State Medical Association; aged 64; died, April 11.

Harry J. C. Maus, Detroit; Michigan College of Medicine and Surgery, Detroit, 1904; aged 60; died, April 5, in the Lincoln Hospital of lobar pneumonia.

George Elmer Porter, Warehouse Point, Conn.; Dartmouth Medical School, Hanover, N. H., 1892; aged 70; died, April 11, of cerebral embolism and myocarditis.

José Ramon Alvarez, Havana, Cuba; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885; aged 73; died, April 12.

James M. McPherson, Terral, Okla. (licensed in Oklahoma under the Act of 1908); member of the Oklahoma State Medical Association; aged 78; died, April 29.

Jesse Edgar Wright, Macon, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; aged 64; died, March 21, of cirrhosis of the liver.

Newell Cutler Bullard, Cambridge, Md.; University of Vermont College of Medicine, Burlington, 1898; aged 64; died, April 20, of cerebral hemorrhage.

William Henry Baxley Jr., Hephzibah, Ga.; University of Georgia Medical Department, Augusta, 1887; aged 74; died, April 22, of coronary thrombosis.

Eleanor Tomes, New York; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1892; aged 88; died, March 3.

Jesse Belmont Rogers Ⓢ Michigan City, Ind.; Hahnemann Medical College and Hospital, Chicago, 1895; aged 72; died, April 22, of bronchial asthma.

Minnie Ridgeway Bishop, Chicago; Hahnemann Medical College and Hospital, Chicago, 1889; aged 77; died, April 13, of bronchitis and myocarditis.

Ralph Gordon Turner Ⓢ Walpole, Mass.; Rush Medical College, Chicago, 1933; aged 31, died, March 26, of pulmonary and intestinal tuberculosis.

John Roy Mackenzie, New Rockford, N. D.; Detroit College of Medicine, 1906; aged 57; died, April 10, in a hospital at St. Paul, of heart disease.

GONORRHEAL ENDOCARDITIS

To the Editor:—In a letter to the Editor in *THE JOURNAL*, May 14, Dr. Merrill finds fault with the criteria that we consider essential in making the diagnosis of gonorrheal endocarditis. In doing so he has taken one sentence out of the first paragraph in the second column on page 549 in *THE JOURNAL* of February 19 and disregarded the preceding and subsequent sentences. In that paragraph it is stated that "the diagnosis of gonorrheal endocarditis depends on a heart lesion developing suddenly in the course of a systemic complication of gonorrhea" and that for an absolute diagnosis a positive blood culture *in vivo* or a recovery of the gonococcus from the heart valves is essential. Any one who reads this entire paragraph will find no reason for any disagreement.

With respect to the seven cases cited as proved cases I wish to refer to the original articles. My co-authors and I quoted enough from each one to indicate that the patient had a gonorrheal infection and the nature of the treatment as well as the outcome. We are not inclined to doubt the clinical ability of the respective authors quoted.

We did not think it necessary to insert the type of hemoglobinometer employed. The laboratories of Harper Hospital use the Salhi instrument. Dr. Merrill states that there was only a single observation of 63 per cent hemoglobin made. If he will read the last part of the case report it will be found that four months after discharge the hemoglobin of the patient was 81 per cent.

With respect to the statement that an anemia will produce a murmur, there is no argument. However, right under our eyes this patient acquired a murmur of increasing intensity in the aortic area, where previously a soft systolic murmur at the apex, not transmitted, was all that was audible.

This aortic murmur not only persisted during the entire course of the disease, but months after, when the hemoglobin had risen and all clinical signs of gonorrhea had vanished, the new murmur which developed during the course of the disease still persisted. If one had seen the cardiac picture of this woman when she was brought into the hospital, watched it change during the weeks of her illness, and then four months later examined her again, one would be forced to conclude that an active endocarditis had taken place and that definite valvular damage had been wrought.

HUGO A. FREUND, M.D., Detroit.

MASSIVE ATELECTASIS WITHOUT BRONCHIAL OBSTRUCTION

To the Editor:—Kaunitz (*THE JOURNAL*, May 21, p. 1770) has questioned the possibility that massive atelectasis may, in rare instances, occur without bronchial obstruction. At first we seriously questioned this possibility ourselves, realizing that the idea ran counter to existing experiments and conceptions. Our belief is that atelectasis, in the vast majority of cases, is due to pulmonary obstruction. But enough clinical evidence now exists to deny that atelectasis cannot possibly develop without obstruction.

We feel that nothing has been postulated in this connection (a position claimed as too plain to require proof). One of us became acquainted with the persons and facts concerned in three most dramatic, unfortunate and unexplainable results of anesthesia. At necropsy, obstruction was not found. If our report of these cases failed to state definitely that obstruction was not found, we apologize. The pathologists in two of the cases were most emphatic. In the third case, Dr. Guedel wrote us that obstruction was not seen in the parts of the bronchial tree that were examined.

Since our paper was offered, another case of death on the operating table of massive atelectasis is available in which obstruction was carefully sought and not found at necropsy. This will be published soon in *Anesthesia and Analgesia* together with a full discussion of the work of Lorrain Smith (referred to by Dr. Kaunitz) and many others concerning oxygen poisoning. With the publication of this case there will be in the literature seven cases of sudden death under or immediately following anesthesia from massive atelectasis, in which necropsy showed no trace of obstruction in the bronchial tree. This is not postulation: it is the proof itself.

Intrapleural and atmospheric pressure differences do not eliminate the possibility of atelectasis without obstruction. S. J. Meltzer (On the Respiratory Changes of the Intrathoracic Pressure Measured in the Mediastinum Posterior, *J. Physiol.* 13:218, 1892) long ago showed that negative pressure differences initiated by respiration, which are primarily dependent on the differential of atmospheric and intrapleural pressures, are not uniformly transmitted through the pleural cavity.

The total of vital capacity plus residual air in the average chest is about 5,000 cc. Thus when 300 or 400 cc. of gas is drawn into the lungs at each breath during quiet depressed respiration it is quite unlikely that this small amount disseminates to all parts of a space capable of expanding to a total of 5 liters, no matter what the pressure differential.

Air does not go into and out of the lungs as though they were simple balloons being inflated and deflated. The anatomic studies of Keith (Further Advances in Physiology, edited by Leonard Hill, London, Edward Arnold, 1909, p. 182) have shown that different parts of the lung expand at different times in a manner comparable to the opening of a Japanese fan. Some parts of the lung may not be ventilated at all for a considerable interval. In line with this conception Haldane and Priestly (Respiration, Yale University Press, 1935, p. 41) and again Schmidt (Macleod's Physiology in Modern Medicine, St. Louis, C. V. Mosby Company, 1938, p. 485) call attention to the wide variations that exist, during shallow respiration, in the composition of the alveolar air from different parts of the same lung. If during these intervals, under anesthesia, only the rapidly absorbable gases are present a small area of atelectasis could readily be established and could continue to spread as a creeping process until terminated by demand for more lung absorption surface.

That such a process does go on during and following anesthesia can be inferred from the work of Muller, Overholt and Pendergrass. (Postoperative Pulmonary Hypoventilation, *Arch. Surg.* 19:1322 [Dec., part 2] 1929). These investigators showed a marked shrinking of the lung accompanied by an elevated diaphragm, vital capacity reduced to a third of normal and tidal volume reduced one half, in uncomplicated postoperative cases. Pressure differentials seem to be unable to prevent these results.

Dr. Kaunitz suggests that possibly either (a) bronchial spasm, (b) obstruction by the tongue or (c) breathing against a collapsed bag might explain the cases reported in our paper. The first suggestion has been argued for years but the weight of existing evidence is against it. (Coryllos, P. N.: Postoperative Pulmonary Complications and Bronchial Obstruction, *Surg., Gynec. & Obst.* 50:795 [May] 1930.) Certainly bronchial spasm clinically does not produce atelectasis; quite the opposite. The second and third suggestions, besides being inexcusable anesthesia practice, are unsuited to explain our reported cases. For instance, in one case collapse developed with an endotracheal tube in place, effectively eliminating the factor of tongue obstruction. Furthermore, breathing against inspiratory obstruction, such as would be produced by a collapsed breathing bag, produces pulmonary edema, not collapse (Moore, R. L., and Binger, C. A. L.: The Response to Respiratory Resistance, *J. Exper. Med.* 45:1065 [June] 1927).

Finally, the fact that animals are able to exist for varying periods in oxygen rich atmospheres was brought out as an objection. This opens the extensive subject of oxygen poisoning. But it should have been added how they live: in preparation of death. High tension oxygen atmospheres were demonstrated as being universally fatal for warm blooded animals by the work of Binger, Faulkner and Moore (Binger, C. A. L.; Faulkner, J. M., and Moore, R. L.: Oxygen Poisoning in Mammals, *J. Exper. Med.* 45:849 [May] 1927. Faulkner, J. M., and Binger, C. A. L.: Oxygen Poisoning in Cold Blooded Animals, *ibid.* 45:865 [May] 1927).

We are familiar with the work of Fine, Hermanson and Frehling (Further Clinical Experiences with 95 Per Cent Oxygen for the Absorption of Air from the Body Tissues, *Ann. Surg.* 107:1 [Jan.] 1938) with high oxygen concentration in man. The conditions under which they worked are not comparable to those used with experimental animals. Frequent interruptions for nursing care and treatment were necessary.

Binger and his co-workers quote one instance from the German literature of changes produced in a dog's lungs within fifteen minutes by inhalation of pure oxygen, although this is unusual. In oxygen poisoning the lungs at necropsy are found "collapsed" (their word), airless and sink in fixing fluid. The blood vessels are engorged. This much of the picture simulates massive atelectasis. But the completed picture is quite different, possibly for this reason. The high pressure head of oxygen allows life to continue much longer than such extensive pulmonary changes would otherwise permit. For instance, Binger took animals out of an oxygen chamber after this condition was well established and produced immediate death. This prolongation of life allows time for further changes in the appearance of the lung. The alveoli refill with red cells and transudate from the engorged lung vessels. The epithelial cells slough, possibly as a result of the existing lung damage, from inadequate exposure to oxygen. The animals all die of severe anoxemia. At least in presenting this guess, no other theory has to be disproved, for no explanation has been advanced to account for the unique pulmonary basis of this mysterious phenomenon, which has puzzled thoughtful men since the time of Paul Bert.

These rare cases of massive atelectasis without obstruction are relatively unimportant. Of greater significance is the possibility that by the use of inert gases in anesthesia a further reduction in the incidence of postoperative pulmonary complications, developing from the widely accepted sequence of bronchial obstruction and atelectasis, may eventuate.

"CHRONIC SUBDURAL HEMATOMA WITH ACUTE PSYCHOTIC MANIFESTATIONS"

To the Editor:—With regard to the article by Dr. D. M. Olkon on chronic subdural hematoma with acute psychotic manifestations (*THE JOURNAL*, May 14, p. 1664) it appears to me that the patient mentioned had an additional diagnosis, that of bromide intoxication, which if true could easily have been confirmed by a blood bromide determination. In the first place there is a history of bromide intake: "He took 'bromo-seltzer' three or four times a day." I infer that this intake continued over a period of about one year since the "bromo-seltzer" was taken for headaches, which began about a year before the patient came under Dr. Olkon's care and "continued." A patient in our series of twenty-one cases of bromide intoxication (Burns, G. C., and Henderson, J. L.: Bromide Intoxication, *California & West. Med.* 46:392 [June] 1937) had a similar history of having taken "bromo-seltzer" in excessive quantities, as a result of which he contracted a bromide intoxication. His symptoms were such that the diagnosis was thought to be dementia paralytica and it was only after the laboratory

returned a negative report on the spinal fluid that a test of the bromide content of the blood was taken. This showed 250 mg. per hundred cubic centimeters. Another patient in our series showed a tendency to stagger, stumble and fall five months prior to admission, apparently the result of bromide intoxication, since she had been taking bromides for two years prior to her admission. This is comparable to Dr. Olkon's patient, who "had a tendency to stumble and fall" about six months before the onset of his acute symptoms.

Dr. Olkon's physical, neurologic and psychiatric observations are all typical of bromide intoxication. The psychiatric picture in particular is that of an acute organic reaction, a toxic delirium with confusion, disorientation and a tendency to misidentify even his nearest relatives. In particular the hallucinations were vivid and terrifying and he tended to react to them acutely and promptly. This mental picture is very different from the usual dull retarded stuporous, even comatose, symptoms typical of subdural hematoma, which of course Dr. Olkon recognized and is his reason for reporting the case: "Careful search of the literature did not reveal any case of chronic subdural hematoma in which mental features were predominating and the organic manifestations mainly absent; for these reasons this case is reported." The average hospital diet contains enough chlorides to replace bromides to the point at which such symptoms would disappear in two to three weeks. In any event I feel that bromide intoxication should be ruled out before these symptoms are attributed to chronic subdural hematoma.

J. L. HENDERSON, M.D., Compton, Calif.

Resident Physician, Compton Sanitarium.

ACTION OF HYPOGLYCEMIA ON NERVOUS SYSTEM

To the Editor:—I read with great interest in *THE JOURNAL*, April 30, some observations on the action of hypoglycemia on the central nervous system by Dr. Ernst Gellhorn.

May I venture to offer a somewhat different explanation of the benefits of hypoglycemia in schizophrenic patients. It is agreed that there is a reduction in the oxidation rate and sugar consumption in the central nervous system, as proved by Himwich, but I do not believe that there is much evidence to sustain the opinion that the sympathetic centers are stimulated by this regimen, except as a result of the dominance of the vagus in the hypoglycemic state and the subsequent calling into play of the principle of homeostasis. The sympathetic discharge probably comes at the end of the treatment, as Dr. Gellhorn himself has noted, but I believe the benefits derived are rather due to the preliminary vagotonic state.

May I refer to some observations of my own in a discussion on this whole subject at a meeting of the Section of Neurology and Psychiatry of the New York Academy of Medicine, held on Oct. 12, 1937, and reported in the *Archives of Neurology and Psychiatry* (39:853 [April] 1938). In this discussion I said:

The effect of insulin seems to be, as Dr. Himwich has demonstrated, a reduction in the entire metabolism of the brain. There are indications during this phase that the vagus nerve begins to dominate the scene. One notes, for example, vomiting, sweating and bradycardia—evidences of increased vagal tone. Dr. Sakel has spoken of vagotropic effects and the use of insulin to paralyze adrenal activity. I wish to expand on this vague concept and to stress the neurophysiologic mechanisms involved. The vagus nerve is the regulator of anabolism, the great conserving force in human economy. It dominates in hibernation states, when the vital forces must be husbanded—witness the bradycardia, low blood sugar and lowered metabolism in these states. It counteracts the effects of sympathetic domination, in which all the fighting resources of the body are mobilized for defense, as has been pointed out by Cannon.

Insulin treatment, therefore, is a form of protective therapy. It seems that the effect of insulin is to reduce the tempo of the whole vital process in a person who is battling with all sorts of complexes, panics and threats to the ego, with consequent mobilization of all the resources of

defense, in a struggle which results not in success but in the patient's becoming ill. The effect of insulin, then, is to spare these fruitless expenditures of energy and protect the patient against this fitful, anarchic discharge of energy.

This method of therapy is also protective on the psychic side. It is a form of necrosis therapy, with blotting out of the abnormal activity of the mind consequent on the states of panic and threats to the ego already spoken of. These are held in abeyance because, so far as is known, in the well developed narcissis no psychic processes go on and the person in this state is spared the necessity of thinking about his problems. This may explain the favorable effects of sodium amylal narcissis reported from so many sources. As a result of blotting out the abnormal activity of the mind, the organism recuperates, and, owing to the inherent factors of safety in the human organism stressed by Meltzer and others, the patient returns to the problems of living with a fresh approach and begins to function anew.

This subject is vital and represents a totally new approach to the human mind. The brain is now being considered as an organic unit in the human body and subject to the same biochemical and neurophysiologic mechanisms which obtain in other parts of the human economy.

E. D. FRIEDMAN, M.D., New York.

ERGOTAMINE TARTRATE IN MIGRAINE

To the Editor:—A patient with severe migraine headaches has been studied from an allergic point of view and all substances to which she shows any response of an allergic type have been eliminated from her diet. Typical attacks are preceded by a twenty-four hour period of exhilaration, one-sided headaches coming on at the end of this time, usually on the left side. There is a visual aura. She is, so far as I can determine, in perfect health otherwise. Her past history is negative; her menstrual history is normal. She has one child, aged 5. I have been using ergotamine tartrate in 1 cc. doses. One dose always is sufficient to relieve her headache. A 0.5 cc. dose, however, does her no good. For the first month or two during which I treated her she had headaches at intervals of from ten days to two weeks. For the past two months, however, her headaches have become increasingly frequent and in the last ten days she has had four attacks, each responding within two or three hours to the injection of ergotamine tartrate. I am well aware of the danger in long continued use of ergot preparations but I am not able to discover the amount of ergotamine tartrate that produces these effects. Is there any other means of bringing prompt relief from these headaches? Should I discontinue the use of the ergot preparations and try to rely on the usual sedatives? About how long a time is required for toxic properties of the preparation to produce circulatory or nervous symptoms? Is it possible to have migraine headaches at as short intervals as this patient apparently has them?

M.D., Texas.

ANSWER:—There seems to be no reasonable doubt about the diagnosis. The patient has the usual visual aura followed by hemicrania. She has, moreover, been relieved in the past by ergotamine tartrate. The fact that the headaches are increasing in number, with a short interval between them, suggests other factors which are not entirely compatible with the diagnosis. It is unusual for patients to increase the frequency of their attacks. Because of this the patient should be thoroughly rechecked, special attention being paid to a possible endocrine imbalance.

Specifically it may be stated that no other drug gives such prompt relief in migraine as ergotamine tartrate. If toxic manifestations from ergot are beginning, the patient will first note a persistent numbness and tingling of the extremities, possibly with some evidence of peripheral vasospasm. It is considered inadvisable to give ergotamine tartrate, either subcutaneously or intramuscularly, in more than 1 cc. doses, administered in twenty-four hours, nor more than two such injections in any one week. In some patients this dosage may cause signs of ergot poisoning and a good general rule would be to use not more than 1 cc. per week. Some relief may be obtained by the use of a readily assimilable calcium compound, such as calcium gluconate, 4 Gm., two or three times a day. Further discussion of this subject can be found in the article by von Storch to be published in *THE JOURNAL*.

POSSIBLE TYPHOID FEVER

To the Editor:—A boy, aged 14, one of three children with typhoid, had a typical typhoid course for approximately seven weeks. Fever ranged from 99.5 F. in the morning to 103.5 in the afternoon. He has completely recovered. The Widal test and culture were both positive. However, a sister, aged 10, became ill about three days after him with fever and mild headache. Her temperature varied from 99 to 100 F. For the past forty-five days her fever has appeared from one to four hours only during the afternoon. She has had fever for ninety days to date. Another sister, aged 7, became ill two or three weeks after the brother and her temperature has taken about the same course as her sister's, around 99 to 99.5 F., for about seventy days. No blood test or culture was made on the girls. The sisters have never been very sick and except for a little rise in temperature are normal in every respect. All other examinations were negative. Would you consider the duration natural and continue to keep them in bed, with proper food and nursing? What are the possibilities of some hidden complication and where would you suggest looking for it? Is there any drug that might hasten recovery?

M.D., Texas.

ANSWER:—The diagnosis of typhoid in the case of the girls mentioned in this question was entirely warranted by the circumstances but the clinical course has not been that of typhoid. Typhoid in children may show aberration from the adult form but as a general rule the course of the disease is shorter than in the adult. "Ambulatory typhoid," or typhoid with low fever, does occur but it is rather rare and it would be unusual to have two such cases at one time. This situation requires the application of accurate diagnostic measures. If the girls have typhoid it may be demonstrated by the serologic reaction and the isolation of typhoid bacilli from the stools. It seems more than likely that the cases will prove to be something other than typhoid. If this is true it will be necessary to work through the list of causes of long continued fever. Only by this procedure can one arrive at a correct diagnosis. Among the more common causes for this clinical picture are mediastinal adenitis, infectious mononucleosis, and rheumatic fever. Tuberculosis must be ruled out, although this disease in children is likely to take a much more stormy course than that described.

If the cases prove to be typhoid, the only treatment is continued time and patience. It is difficult to see what complication of typhoid could be present without becoming quite obvious after such a period.

STERILIZATION OF RUBBER BOOTS AND SHOES

To the Editor:—What is the simplest and most effective method of sterilizing rubber boots, leather shoes and clogs, suitable for an industrial organization? Steam sterilization tends to devitalize rubber and hardens leather. Gas would be preferable to a liquid chemical.

GEORGE M. BLANK, M.D., Lorain, Ohio.

ANSWER:—The majority of agents that might provide disinfection are prone to damage the articles mentioned. Formaldehyde makes leather brittle, sulfur attacks metal parts, various possible hydrocarbons may dissolve or attack rubber. Glues used in connection with footwear may be dissolved by many liquids. Penetration is slight by fumigation; sunlight or artificial ultraviolet rays may not be introduced readily in most instances. In the case of wooden clogs there can be no objection, except in connection with fading, to submersion in a chlorine liberating solution or appropriate solutions of commercial agents, such as saponated solution of cresol. In the case of rubber boots and leather boots or shoes the use of dusting powders is likely to yield unsatisfactory results or to cause dermatitis to the subsequent wearer. Many organisms are short lived and will die if the articles are not worn for a few days. Exposures to intense sunlight will be of some value, but obviously penetration is not possible in many instances. If the matter is limited to the occasional disinfection of a single pair of shoes, thus not warranting elaborate equipment, it is possible that the best results may be obtained by a generous sponging with a phenolic solution or equivalent coal tar bodies. This will not yield perfect results.

Special ultraviolet equipment may be introduced into the individual shoe or boot as may be required. This will represent an expensive, time consuming and somewhat practical procedure. Hydrocyanic acid fumigation, carried out in gas tight cabinets under safe conditions, will be effective in killing off animal parasites but is of little value as a germicide. The prospective results from this procedure do not warrant the required outlay. If any chemical agent is used, extensive airing of the boots and shoes is a prerequisite to rewearing. In general this problem tends to resolve itself into the practice of procuring conditions with reference to footwear that will make sterilization or disinfection unnecessary.

DEXTROCARDIA WITH SITUS INVERSUS

To the Editor:—A boy, aged 12 years, on careful x-ray examination is shown to have dextrocardia. In addition, his stomach, liver, kidneys and cecum are reversed. Will you please advise me regarding the frequency of this condition?

L. C. CHADSEY, M.D., Brockville, Ont.

ANSWER.—Congenital dextrocardia with or without the situs inversus is a rare condition. Dextrocardia without transposition of the abdominal viscera is almost always associated with other structural defects in the heart, but the heart is likely to be normal in instances such as that noted of dextrocardia with the situs inversus. In Dr. Maude Abbott's statistics of congenital heart disease among 1,000 cases analyzed by her, fifteen were of dextrocardia with situs inversus, four of which complicated other defects.

There are, so far as is known, no complete statistics of this type of dextrocardia in the population at large but there are a few suggestive studies, one of which was the analysis of Boston School Children some years ago. Among 27,900 school children from four districts in Boston (West End, North End, Charlestown and East Boston) there were three cases (0.01 per cent) of congenital dextrocardia with the situs inversus. Probably this is not far from the true incidence of congenital dextrocardia with the situs inversus in the population at large.

INSULIN AND HEXYLRESORCINOL ORALLY

To the Editor:—What is the present status of insulin by mouth with hexylresorcinol?

GUY E. FINZLE, M.D., McPherson, Kan.

ANSWER.—The present status of the administration of insulin by mouth with hexylresorcinol is purely experimental. Daggs, Murlin and Murlin (*Ann. J. Physiol.* 120:744 [Dec.] 1937) reported that they obtained a significant fall in the blood sugar in only about 50 per cent of dogs so treated. A fall of 20 mg. or more per hundred cubic centimeters was considered significant. But these animals were made to fast for sixteen hours prior to the administration of insulin and were given from 100 to 250 units of insulin at a dose. Furthermore, even when a fall in blood sugar did occur, it was not maintained for more than two or three hours.

These results are interesting and hopeful but, even if confirmed by others, the practicability of their application to the treatment of diabetes mellitus is doubtful.

HYPERTENSION AND DECOMPENSATION

To the Editor:—A white woman, aged 52, who has been known to have hypertension for five years, suddenly had two successive attacks of transitory blindness in the right eye. Examination showed a normal disk, sclerotic arteries with crossing compression of the veins, and no exudate or hemorrhage, but a dilated pupil responding poorly to light in the right eye. The blood pressure is 180 systolic, 120 diastolic. Several days later, general weakness and drowsiness prompted a determination of the non-protein nitrogen, which was found elevated to 60 mg. per hundred cubic centimeters. Fluids by mouth were then forced and hot pads applied to the back for a week, when a second test showed 32 mg. of nonprotein nitrogen per hundred cubic centimeters. At this time the patient felt much stronger and no longer drowsy. Repeated urine examinations showed no dextrose, albumin, casts or red cells and a specific gravity of 1.016. The output of urine on forced fluids was from 2 to 2.5 liters. Until the attack of blindness the chief complaint was inability to walk more than a block without fatigue and dyspnea. There appears to be a mild ascites but no ankle edema, sacral edema, cyanosis or orthopnea. In a period of one year there has been a gain of 14 pounds (6.4 Kg.) without any increase in appetite. The pulse rate is 80. The following statements appear likely: The patient has latent edema, and this and the mild ascites are due to beginning congestive heart failure secondary to the essential hypertension. The patient has considerable kidney damage, presumably due to prolonged hypertension, and accumulation of nonprotein nitrogen is prevented only by a free, large intake of fluid. (Incidentally, on bed rest and sodium nitrite, the patient's blood pressure came down from 180/120 to 146/82 and oscillates between these levels.) What methods of combating the congestive failure (which I expect to increase progressively) are available which do not require a restriction of fluid intake? Digitalis seems contraindicated with a pulse rate of 80, and mercurial diuretics also. Is it likely that a vascular crisis causing spasm of the retinal vessels might similarly affect the kidney and cause temporary loss of function, which is responsible for the azotemia observed in this case? What further suggestions for treatment can you make; e. g., pancreatic hormones?

M.D., New York.

ANSWER.—The conclusions as stated are logical and warranted from the data available. The fall in arterial tension from 180/120 to 146/82 with bed rest and sodium nitrite reveals that the arterioles have not yet become extensively sclerotic. Under such circumstances one may hope for better therapeutic results than when the arterioles are rigid and the diastolic tension is fixed.

The acute transient blindness was probably due to arterial or arteriolar spasm of the retinal vessels. The drop in tension with vasodilator medication reveals that the great majority of the vessels are relaxable and therefore also prone to spasm. It is possible, but not probable, that similar renal arterial spasm caused the hyperazotemia. It is more logical to consider that the patient's renal functional efficiency had been impaired for some time with a gradually rising azotemia, discovered at the peak. The primary and fundamental failure of the kidneys in nephritis is depression of the renal ability to concentrate the urine. The response to forced fluids in this instance is illustrative. Under such circumstances as these, there is no alternative but to give the patient's kidneys sufficient water to permit adequate daily removal of the metabolic debris. Renal function studies are in order. At least the concentration test and the urea clearance test should be carried out and repeated at intervals of several months. The technic and interpretations were given in *Queries and Minor Notes* in *THE JOURNAL*, Feb. 8, 1936, page 484.

Despite the additional burden it may place on the heart, a liberal fluid intake is absolutely essential. The burden this engenders can be minimized by spreading the intake out; the patient should consume fluids in small quantities but at frequent intervals. Adequate therapy must invariably take the causation into consideration. Are there any other sources of cardiac injury in addition to the hypertensive arterial disease? Obesity might be one. Coincident anemia would greatly add to the cardiac problem as well as to the renal one. If the hemoglobin content of the blood should be found below 85 per cent by accurate determination, prompt treatment is indicated. The xanthine derivatives, particularly aminophylline or the more soluble and less irritating glucophyllin (a German product containing 10 per cent dextrose and 2 per cent theophylline), may, by aiding the coronary circulation, do much to support the myocardium. An adequate supply of available dextrose is important; cardiac efficiency is often much improved thereby. The most important aid, however, which may be given this heart is in reducing the burden of required work. This means reduction of the diastolic tension for a long period. The vascular sedatives, such as sodium nitrite, bismuth subnitrate (0.6 Gm., or 10 grains, thrice daily) or small doses (0.03 Gm., or one-half grain) of erythroltetranitrate should prove of value. If apprehension or high nervous tension are considered factors elevating the arterial tension of the patient, moderate doses of bromides (approximately 0.6 Gm., or 10 grains, thrice daily) may be of aid. The thiocyanates, although effective arteriolar sedatives, are not safe, particularly in this instance with definite renal impairment. The larger fluid intake should also contribute toward reduction of the hypertension. The various tissue extracts, among which insulin free pancreatic extract is perhaps the best known, have vasodilator properties similar to adenosine. But the fact that they must be administered hypodermically at frequent intervals over many months makes this form of vascular sedation impractical.

If the patient is overweight, gradual reduction is highly desirable. Radical restriction of the protein intake is contraindicated; it would aggravate any tendency to anemia and edema and be of no benefit in controlling the hyperazotemia. All spices and condiments are best deleted. Salt in small amounts, such as used in ordinary cookery, is advisable. Coffee and tea are permissible except in the late afternoon and evening. The morning stimulation is desirable and caffeine is both a cardiac and a renal stimulant.

LIVER AND IRON IN SECONDARY ANEMIA

To the Editor:—What is the current opinion of authorities doing blood work relative to the value of liver extract given orally in the treatment of secondary anemias? Also I should like to know whether or not such commercial preparations as "Lextron" of the Eli Lilly Company are thought to contain sufficient available iron in the doses recommended for the treatment of secondary anemias.

ROBERT G. PRICE, M.D., Bloomington, Ill.

ANSWER.—In the majority of hypochromic (secondary) anemias it is now generally agreed that there is no advantage in giving liver preparations provided adequate doses of iron salts are used. Adequate doses of iron compounds are: iron ammonium citrate 6 Gm. (90 grains) daily; ferrous sulfate 0.6 Gm. (9 grains) daily; ferrous carbonate 4 Gm. (60 grains) daily. If these doses are used there is no added therapeutic benefit from the use of liver. However, in a few cases of hypochromic anemia complicated by massive hemorrhage, liver extract containing the so-called Whipple secondary anemia fraction may be administered concurrently. Lextron is a proprietary name for a complex product stated to contain in each capsule "liver-stomach" concentrate 0.455 Gm. (7 grains), iron

and ammonium citrate green 0.2 Gm. (3 grains), vitamin B₁ 20 international units, and vitamin B₂ 20 Sherman units. In recommended doses this is equal to from 1.75 to 2.3 Gm. (27 to 36 grains) of iron ammonium citrate green a day. This is obviously not an adequate dose of iron for best results. It is best to give iron first and supplement it with the Whipple fraction of liver only in the few cases of hypochromic anemia if iron compounds alone fail to bring the blood to normal in a reasonable time. Lextron does not stand accepted by the Council on Pharmacy and Chemistry.

POLYPOSIS OR CANCER OF COLON IN CHILD

To the Editor:—A white boy, aged 5, has had recurrent attacks of pain in the abdomen for the past eighteen months. At these times gross pus and blood are seen in the stool. Microscopic examination of the stool shows no specific causative organism. The blood and urine are normal. X-ray examination of the gastro-intestinal tract gives normal results excepting for roughness in the descending colon. This condition was diagnosed by the x-ray department as probable colitis. The patient has passed small globular chunks of well preserved tissue by rectum which microscopically have the appearance of polypoid tissue. From this I have made a diagnosis of multiple polyposis of the colon. Please discuss treatment in a case of this type together with references to the literature.

M.D., District of Columbia.

ANSWER.—Simple polyposis of the colon of the so-called congenital type is said to have its highest incidence in children and young adults. The entire colon is frequently affected, but the process may be limited to the rectum and sigmoid. These portions of the colon are almost always involved and hence a proctoscopic examination should give further diagnostic information. Chronic amebic colitis has apparently been excluded by the failure to find *Endamoeba histolytica* in the stools. So-called nonspecific ulcerative colitis can probably be excluded by the proctoscopic examination, for this disease also almost invariably involves the rectum and is not difficult to differentiate from polyposis except for the cases of chronic and long-standing ulcerative colitis in which secondary hyperplasia and polyposis develop—a situation obviously not obtaining in the case described.

The passage of "small globular chunks of well preserved tissue by rectum which microscopically have the appearance of polypoid tissue" is almost never seen in ulcerative colitis. This statement applies equally to benign polyposis, for in this condition the polyps are firmly attached to the bowel, they are not necrotic, and they rarely if ever slough. The presence of polypoid tissue in the stool suggests the diagnosis of carcinoma. This possibility fits well with the known tendency of benign polyps to undergo malignant transformation—a tendency estimated at from 40 to 50 per cent. Further careful microscopic study of the tissue passed by rectum would probably reveal definite evidence of carcinoma.

If this should be the case, radical surgery offers the only possible hope, but, of course, the prospects for permanent cure are not bright. There are good discussions of the subject and references to the literature in such standard textbooks as "The Colon, Rectum and Anus," by Rankin, Bagen and Buie, and "Proctology," by Yeomans. Ralph M. Larsen described an infectious polypoid colitis (*Arch. Int. Med.* 51:236 [Feb.] 1933) but the case reported bears little resemblance to the one cited.

BLANKETS AND TEMPERATURE FOR INFANTS

To the Editor:—I have been telling mothers who ask how warmly a child should be covered that a thermometer placed between the blanket and the baby should register within a few degrees of 80 F. Is there a range of temperature in that area (i. e., between the blanket and the baby's body) which is considered safest?

M.D., New York.

ANSWER.—No definite answer can be given to the question as to the range of temperature between the blanket and the baby's body. The size of the baby, its age, its subcutaneous tissue and its heat regulating mechanism would all come under consideration in the answer to this question. There must be great individual variations in these various factors in different babies. This becomes at once evident in the care of a large station for premature infants, where it has been noted that babies of equal age and weight will require different incubator temperatures to maintain their normal body temperatures. The incubators must be adjusted in a range from 78 to 90 F. for babies of different age weight.

Another factor would be the texture and quality of the sleeping garment worn by the infant. If the baby was in a heavy woolen sleeping suit, a given temperature between the blankets might be too warm. On the other hand, this temperature might be too cool for the baby if he was dressed in only a

light garment. The temperature of the sleeping room and the thickness and type of mattress would also be factors that would influence the warmth of the infant.

It must be admitted that the modern mother desires and is flattered by specific instructions. She would rather be told the exact temperature to have the baby's bath than to test the warmth of the water with her elbow as the old fashioned mother did. However, owing to the many variables mentioned, it would seem almost impossible to advise her to insert the thermometer between the blankets and advise her the exact degree of Fahrenheit which would be optimal for the warmth of the baby.

It would seem better to advise the mother in the old fashioned common sense way to feel the baby's hands or feet and note whether these are cold or warm or whether the baby is restless or sweating.

VESICOVAGINAL FISTULA

To the Editor:—Is there any satisfactory contrivance to be worn by a woman with a vesicovaginal fistula? This is a recurrent malignant condition which originated in the cervix and was irradiated apparently successfully three and one-half years ago. The woman is in good general condition and probably would have several months to live and go about if she could keep dry.

M.D., Virginia.

ANSWER.—There is no satisfactory contrivance to be worn by a woman with a vesicovaginal fistula. The most satisfactory substance for local application is kaolin ointment prepared as follows: A puddle of liquid petrolatum is poured on a glass slab; Kaolin powder is gradually added and worked into the oil with a spatula. Sufficient kaolin is used to make a mixture the consistency of very thick cream.

ARSPHENAMINES AND BISMUTH BY INUNCTION OR SUPPOSITORY

To the Editor:—Has any effort been made to administer arspenamine, neoarsphenamine or bismuth as an inunction in a suitable ointment base, or rectally in suppository form?

M.D., Louisiana.

ANSWER.—Arsphenamine, neoarsphenamine and bismuth compounds have been administered by inunction in the treatment of syphilis but without success. According to the latest pharmacologic literature on the subject of absorption through the skin (Macht, D. I.: The Absorption of Drugs and Poisons Through the Skin and Mucous Membranes, *THE JOURNAL*, February 5, p. 409) the ordinary fixed oils and fats employed in making ointments are poor carriers for other drugs when penetration into the systemic circulation is the object. The chief exception to this rule among the heavy metals are mercury and inorganic mercurial compounds. With regard to absorption by rectum of drugs introduced in the form of suppositories, the chances for absorption are theoretically more promising but there is no record of the successful administration by that route of the drugs mentioned in the treatment of syphilis.

STRONTIUM BROMIDE

To the Editor:—I should like advice on the advantages and disadvantages of strontium bromide over other forms when bromide therapy is indicated. Would the addition of calcium gluconate increase the value of the bromide prescription?

J. M. BAILEY, M.D., Hopewell, Va.

ANSWER.—The theory that strontium salts would be more slowly absorbed and therefore have a more gradual and milder action has been proved to be without foundation. The strontium salts are more expensive. Calcium compounds are not sufficiently well absorbed to exert a systemic sedative effect.

LIQUID PETROLATUM

To the Editor:—Is there any harm to a patient who takes plain mineral oil daily for many years? Is there any brand of mineral oil that is best, and are all brands sold by druggists in gallon lots just as good as those sold at a much higher price by the physicians' supply houses? One woman patient told me that she has taken mineral oil at night for over twenty years for constipation.

THOMAS C. HINKLE, M.D., Onaga, Kan.

ANSWER.—There is probably no definite or serious harm likely to result from the taking of liquid petrolatum daily even for many years. One objection that has been raised against such a practice is that it may rob the system of fat soluble vitamins. Diversion of fat soluble vitamins may be minimized by administering the oil on an empty stomach. However, a liberal intake of vitamins is likely to compensate for any that might be lost in the oil. There is no essential difference between various brands of mineral oil excepting as to viscosity.

HYPERTENSIVE RETINITIS OR FUNDUS INJURY
FROM BRIGHT LIGHT

To the Editor:—A man, aged 55, left for work one morning feeling in good health. He has no history of previous eye trouble. He was testing light bulbs when a bright light flashed in his face, blinding him in one eye. He immediately reported this fact to his foreman, who disregarded it. His lawyer referred him to me for my professional opinion as to whether the flash of light was the exciting factor in causing his blindness. External examination of the right eye gave negative results. I could find no evidence of malingering after testing him in several ways. Fundus examination showed an old occlusion of the central retinal artery. There is moderate sclerosis of the retinal artery with marked areas of angiospasm. There is a small hemorrhage along the superior nasal artery. The left eye shows similar vascular changes; namely, moderate sclerosis and angiospastic changes. There is a small hemorrhage along the inferior temporal artery, and about the macula are areas of exudate. A diagnosis of old occlusion of the central retinal artery in the right eye was made, with moderate sclerosis of the retinal arteries and hypertensive retinitis with hemorrhage in both eyes, all conditions being due to the cardiovascular status of the patient. Physical examination revealed the heart enlarged and the rhythm normal. The blood pressure was 230 systolic, 130 diastolic. Could the flash of light have been the exciting factor in causing this man to have unilateral blindness?

M.D., Michigan.

ANSWER.—The diagnosis of hypertensive retinitis with hemorrhages is probably correct and that of course is enough to explain the poor vision and optic atrophy. The general picture of cardiorenal disease is sufficient to cause the retinal arteriosclerosis and the occlusion of the central artery.

Any optic nerve change that could come from a flash of light would require months to develop. A flash of light may cause disturbances of the fundus in two ways; usually (the type of condition which is seen following watching the sun during an eclipse) there is a macular edema which may subside and leave no visual disturbance or visible sign. The edema may take the form of a cyst, which may rupture and leave a hole in the macula with a permanent central scotoma and poor vision. This may be followed by a partial retinitic optic atrophy. The retinal blood vessels would not be disturbed in such a case. It is possible, but rarely happens, that optic neuritis may follow severe exposure to light, usually sunlight. This would produce a picture of secondary optic atrophy with slight changes in the retinal blood vessels.

The patient's condition probably was entirely independent of the flash of light. The vision in this eye may have been poor for a considerable period and merely discovered suddenly following the flash of light.

SODIUM THIOSULFATE IN SYPHILIS

To the Editor:—Does the administration of a solution of sodium thiosulfate intravenously have a place in the treatment of syphilis? Is it spirocheticidal? I have a patient with whom the administration of preparations of both arsenic and bismuth must be suspended for some time and for whom the sodium thiosulfate is rapidly clearing up a dermatitis of long standing. Will the sodium thiosulfate also be a factor in the treatment of this patient's syphilis?

M.D., New Mexico.

ANSWER.—Sodium thiosulfate was popularized as a remedy for postarsphenamine dermatitis and certain other metallic poisonings by the work of McBride and Dennie in 1923. The evidence accumulated then and which has continued to accumulate as to its value in the treatment of metallic poisoning is of two varieties. Laboratory studies calculated to measure the excretion of arsenic or of certain other heavy metals in experimental animals and human beings with or without the added influence of sodium thiosulfate have been completely contradictory. Certain investigators have found that the excretion of heavy metals was increased by the use of sodium thiosulfate, while others have found the precise opposite. On the whole the laboratory investigations on this point, both in animals and in human beings, have been incomplete and unconvincing.

There have been numerous reports of the use of the drug in the treatment of exfoliative dermatitis, other types of arsenical treatment reactions, and in other types of skin diseases not associated with the treatment of syphilis. These reports are for the most part of individual cases or of small groups of cases. They deal with arsenical reactions or nonarsenical and non-syphilitic skin diseases, which, without any treatment, have an extremely variable course; and the reports of the value of sodium thiosulfate in these conditions are, to the critical observer, as unconvincing as the laboratory work.

So far as arsenical reactions are concerned, the opinion of syphilologists is divided, one group of observers feeling that the drug is of some value largely on the basis that one or a few patients treated with it have recovered, whereas another group of observers feels that the drug is completely valueless, that the reported recoveries are not adequately contrasted with a control material, and that in the type of cases reported recovery might have occurred as promptly without as with sodium thiosulfate.

The drug has no spirocheticidal action and is completely without value in the treatment of syphilis. It has been uncritically proposed as a method of treatment for so-called Wassermann fast syphilis, but there is no rationale to its use in this condition and no reason to believe that anything is accomplished by its use in any form of syphilis.

As far as known, sodium thiosulfate does no serious harm and it may be a valuable psychotherapeutic measure for both physician and patient in the sense that it persuades both of them that something is being done for the patient's illness.

PREGNANCY AFTER THROMBOPHLEBITIS

To the Editor:—A normal, healthy primipara, aged 24, was observed throughout a normal gestation and delivered normally of a healthy child in 1930. On the tenth postpartum day, after being out of bed in a wheel chair for the first time, the patient had a fever, and phlegmasia alba dolens of the left leg ensued. Blood cultures were negative. Three months' hospitalization followed, and then a very gradual resumption of minimum activity. A moderate varicosity of the left leg and swelling, particularly after unusual activity (dancing) persist with gradual improvement in the degree of swelling. An elastic stocking has been worn with relief. An eminent authority proposes to inject the varicosity following high ligation. Numerous varying opinions concerning the advisability of another pregnancy have been rendered. The attitude of the patient is bitter—she fears a repetition of the experience. If good care under favorable circumstances prevails, is subsequent pregnancy inadvisable? What is the likelihood of sterility following the puerperal fever? Are similar complications more prone to develop once having occurred?

M.D., New York.

ANSWER.—Thrombophlebitis complicating a pregnancy is not likely to repeat itself in a subsequent gestation, particularly when an interval of seven or eight years has elapsed. The leg veins have undoubtedly become obliterated as a result of the thrombotic process. The edema which is present at this time, particularly following exercise, is the result of the obliteration of important venous channels.

In all probability it would be safe for the patient to become pregnant again. An intelligent explanation of the underlying mechanism should result in the proper attitude on the part of the patient. One cannot guarantee that such a complication will not recur but, if experience is of value, one would not expect a repetition of this complication.

The value of high ligation and injection of the varicosity that is present would have to be determined by examination of the patient. This procedure is commonly resorted to with favorable results.

The likelihood of sterility following puerperal fever would depend on the extension of the inflammatory process. The veins of the pelvis may have been involved but the reproductive organs could easily have escaped any extensive injury. If this should be the case, one would expect normal reproductive organs. In the event that the patient fails to conceive after a limited trial, visualization of the reproductive tract by the injection of opaque substances and x-ray studies will determine the patency of the tubes.

ECTODERMAL DYSPLASIA

To the Editor:—A and B are married and have a daughter 15 months old, normal and in the best of health. B, the wife, has a brother, aged 24, with ectodermal dysplasia. This brother has no teeth, a scanty growth of hair around the periphery of the calvaria, a saddle back nose and no sweat glands. His Wassermann test is negative. Another brother had ectodermal dysplasia but died at 18 months. One sister, unmarried, and B are both normal and well. B's mother and father were first cousins; their mothers were sisters. Going back two generations in B's family, there is no known history of ectodermal dysplasia except the two instances mentioned. Examination of A's lineage reveals no known instances of ectodermal dysplasia. What advice can be given to A and B concerning additional children? Is ectodermal dysplasia hereditary? If so, does it follow the sex-linked pattern of hemophilia? Similarly, what advice should be given to B's unmarried sister? Kindly include references in your reply.

M.D., New York.

ANSWER.—With the subject matter concerned in the questions being in the case history stage, categorical answers can hardly be given to these questions. This subject is well discussed in a work by E. A. Cockayne entitled "Inherited Abnormalities of the Skin and Its Appendages" (New York and London, Oxford University Press, 1933). A discussion of this subject, together with pertinent literature and case histories, will be found beginning on page 218.

AMENORRHEA AND DEMENTIA PRAECOX

To the Editor:—A woman, aged 36, never married, began scanty menstruation at the age of 14. Until about six months ago she was healthy in every way except that there was only occasional menstruation. She has never suffered headaches or cramps or had any signs of the usual trouble expected with so definite an absence of menstrual flow. She has a sister one year older, who has had the same experience but is married and has one child. The patient developed dementia praecox about six months ago. She was violent and uncontrollable and required morphine and scopolamine with restraint for several weeks. She was given within a month about twenty-five injections of theelin in oil, 2,000 units each. She improved promptly and menstruated a slight amount on one day only, two weeks after the last injection of theelin of that course. She later suffered from terrific headaches, which have continued until the last few days, when they have been relieved by daily injections of 0.5 cc. of gynergen (ergotamine tartrate) supplemented by oral administration of ergotrate, the maleate of the new ergot base (to which the name ergonovine was given by the Council on Pharmacy and Chemistry), made by Eli Lilly. At the present time she is receiving more theelin in the dosage of 10,000 units daily and gynergen occasionally. What is the opinion of this type of medication? Would you suggest more theelin? If so, how much? Would you suggest some corpus luteum? I shall be glad to have any suggestions as to future treatment or advice.

M.D., Indiana.

ANSWER.—Not much is known about the specific cause or causes of dementia praecox. It is conceivable that such an illness may result from biologic or psychologic factors or, more likely, both. Proper psychiatric care in addition to injections of endocrine substances would undoubtedly be excellent treatment. Injections of theelin or progynon, the latter given in doses of 2,000 rat units twice a week for a period of about a month, might be tried. Should the patient not improve, insulin or metrazol treatment at a later date might be considered.

"WHITE FINGERS" FROM OPERATING AIR HAMMERS

To the Editor:—I have recently discovered among our employees operating light air hammers a vasospastic condition affecting one or more of the fingers used to guide the hammer. The hammers weigh from 5 to 7 pounds and have a frequency of 3,000 strokes per minute. The vasospasm is noted only when the hand is exposed to cold. This condition has been named stone cutters' disease and pneumatic hammer disease. I should be grateful to you for any information you may have concerning the etiology, pathology and treatment of this condition. Is this a compensable occupational disease?

M.D., Michigan.

ANSWER.—This query describes a characteristic industrial disease known as "white fingers." It may be the same as the disease termed "dead fingers," perhaps first described by Loriga in 1911 and later by Barnes of St. Louis. In this country, chief attention to it has been found in Milwaukee, the stone cutting areas of Indiana, and the automobile industry of Detroit. Although in pneumatic hammer work a variety of occupational diseases may arise, in this particular condition the part played by cold is essential. Clearly it may be differentiated from chilblains, neuritis, neuroses, Raynaud's disease, acroparesthesia, erythromelalgia and scleroderma. The chief features of white fingers are the following:

1. It is not symmetrical as a rule.
2. It is limited to workers manipulating vibrating tools under conditions providing exposure to cold.
3. On right-handed persons it usually affects only the fingers of the left hand.
4. It is not associated with pain, redness or edema.
5. There are no sensory changes of a persistent character.
6. No changes occur in the blood vessels.
7. There is absence of muscular weakness, tremors or cramping.
8. It affects only the fingers, usually starting with the index finger on the outer half, and it does not extend up the hand or arm.

This disease and others from which it must be differentiated are well described in the League of Nations' Encyclopedia of Occupation and Health under the section devoted to pneumatic tools. The disease frequently is disabling for customary work and may prevent such other activities as the driving of an automobile. When once well established during a given winter, it may not disappear until the coming of warm weather. Obviously, it may be prevented by the provision of work conditions freed from low temperatures. However, some benefit may be derived from changing the size of the grasped portion of the tool, by cushioning the tool with cork or sponge rubber, and by lowering the rate of vibration. Temporary relief may be procured by massage or by hot water baths. The disease is compensable when disability arises, in all states providing blanket coverage for occupational diseases. In certain states operating under scheduled systems for occupational diseases coverage, compensation might be provided because of liberal interpretation of the unusually included item "compressed air disease." What may take place in the state of Michigan is

uncertain, since the new occupational disease law in that state has not led to any considerable number of decisions. However, under Michigan's new occupational disease reporting law, every instance of the condition should be reported.

HEMIATROPHY OF JAW

To the Editor:—A girl about 15 years of age has an inequality in the development of the lower jaw. One side is slightly smaller than the other. So far as I can learn there is no definite known cause for this. I would appreciate some information as to the probable cause and the treatment, if any.

M.D., North Carolina.

ANSWER.—Hemiatrophy is a perplexing problem, as its etiology is obscure. It is usually confined to the face either as a whole or principally to the areas supplied by the individual branches of the fifth nerve. There is at times a history of a forceps delivery, but there is little evidence that forceps injury can be the actual cause.

In one case the mother had atrophy of the left side of the face but no other pathologic condition except a malocclusion of the teeth, while her daughter, aged 6 years, had not only typical atrophy of the left side of the face but an adhesion of the tongue to the mandible and side of the pharynx, the left arch of the palate being elevated by the attachment.

Atrophy in general may be from malnutrition, senility, disuse or pressure, but hemiatrophy, whether localized in the face or a complete hemiatrophy of the body, seems to present more evidence of a neuropathic influence. Atrophy of the side of the face occurs at times in lesions of the fifth nerve, in some cranial lesions and wasting of the skeletal muscles in destruction of the anterior cornu of the spinal cord.

Thyroid has been mentioned as being beneficial but in most such cases improvement seems to be quite hopeless.

Benjamin Feinsilver and Herman M. Rosow reported a case of total hemiatrophy in *THE JOURNAL*, January 29, page 366, and gave a bibliography up to 1932.

PRINTERS' SPRAY AND METHYL ALCOHOL

To the Editor:—A spray which I understand is used generally in the printing trades consists of essentially denatured alcohol, gum arabic and gum tragacanth. Printers breathe this spray and in a room where several sprays are in operation the room is rather foggy with it. The men do not seem to be particularly affected. Over a period of years, may it be injurious to their health? How much danger is there from the denatured alcohol made up in accordance with the formula which contains methyl alcohol as a denaturant?

H. G. MURRAY, M.D., Framingham, Mass.

ANSWER.—The trade practice mentioned in this query has come into wide application in offset printing work. In addition to the ingredients mentioned, some use may be made of starch and glycerin. In one recent instance a definite anaphylactic asthma in a printer was traced to the sensitizing action of gum arabic used in these sprays and apparently the difficulty was eliminated by substituting starch for gum arabic. The chief complaints that have arisen center not about the liquid spray but about the dust created, since rapid drying of the spray is essential to the process. This means that the alcohol, with the possible content of 5 per cent methyl alcohol, is quickly evaporated and is present as a vapor. A denaturant of less dangerous nature than methyl alcohol is to be preferred. Additional experience may establish the necessity for the installation of an exhaust system to remove both vapors and dusts in order that printers may not be exposed. If long continued exposure is to be encountered, such systems may be useful as precautionary measures.

RESISTANT UROLOGIC INFECTION

To the Editor:—In attempting to treat with mandelic acid a patient who has consistently shown 2 plus and 3 plus pus in the urine I have never succeeded in securing acidification of the urine greater than a pH of 6 in spite of large doses of ammonium chloride, which I have used in conjunction with several preparations of ammonium mandelate. I believe that if I could secure acidification of the urine I could expect a decrease in the urinary infection, in view of my results in previous cases. I would appreciate information relative to securing the necessary acidification so essential in mandelic acid therapy. The urinary infection apparently dates back six years to an attack of urinary lithiasis, which necessitated operative removal. Since then he has had periodic attacks of fever associated with urinary symptoms.

ALBERT IRVING CLARK, M.D., Galveston, Texas.

ANSWER.—Such difficulties are frequently encountered. A complete urologic investigation should be carried out in order to eliminate the possibility of any complicating factors prolonging the infection or interfering with proper therapy. Cultures of the urine should be made, as the infecting organism in this case may belong to the genus *Proteus*, and in such instances

proper acidification to allow the use of mandelic acid is impossible. If after a complete urologic check there are no complicating factors which must be treated first, sulfanilamide therapy may be tried. Two Gm. (40 grain) doses daily for a period of one week out of every three over a period of two months will probably be required. During the administration of this drug the patient should be under the care of the physician and should be observed frequently in order to guard against any untoward reactions. Further study of the urine should be made for the presence of cocci and, if these are present, all foci of infection should be investigated and eradicated if possible. Coccal organisms occasionally respond well to intravenous injections of neosarsphenamine in 0.2 to 0.3 Gm. doses given five days apart, and not more than two injections should be given. The latter drug should never be given while the patient is taking sulfanilamide.

WASSERMANN FAST SYPHILIS

To the Editor:—A white woman aged 22 had mucous patches in January 1934. The Wassermann reaction was 4 plus. She was given injections of neosarsphenamine 0.6 Gm. and bismuth salicylate in oil (amount not known) weekly. The Wassermann test became negative in four months. This treatment was continued until June 1934, when she had a rest period of two months. This was followed by similar treatment until March 1935. The Wassermann reaction remained negative. In November 1936 the Wassermann reaction was 4 plus. She was put on bismuth salicylate in oil 2 cc. weekly for twelve injections and then returned to the bismuth salicylate for a similar course. The Wassermann reaction was then 2 plus. Another course of neosarsphenamine 0.6 Gm., of twelve weekly injections, was followed by a course of bismuth salicylate in oil. The Wassermann reaction was then 3 plus. The patient was put on mapharsen 0.06 Gm. for twelve weeks and is now getting aqueous bismuth subtartrate 3 per cent 1 cc. twice weekly and saturated solution of potassium iodide 15 drops three times a day. The Wassermann reaction is now 4 plus. Spinal fluid examination last month gave entirely negative results. The patient is 5 feet (152 cm.) tall and weighs 99 pounds (45 Kg.). Physical examination, including neurologic, ophthalmologic, cardiac and hepatic tests, give negative results. Since coming under my observation she has had no rest periods. Please outline further treatment. Is the patient infectious? If the patient becomes pregnant and continues treatment, would she deliver a normal, healthy baby? Would you consider her Wassermann fast?

M.D., New York.

ANSWER.—The definition of Wassermann fastness, either in early or in late syphilis, is arbitrary. In early syphilis the term is usually applied to those cases in which the serologic test remains persistently positive under treatment for six months or longer; in late syphilis to those in which the tests remain positive for one year or longer. According to this definition the patient described is Wassermann fast. In all probability the factor accounting for the persistently positive blood Wassermann reaction is the intermittent treatment with interpolated rest periods within the first two years of her infection.

The variation in her Wassermann test since November 1936 from 4 plus to 2 plus, 3 plus and then 4 plus again is of no significance or importance and may be ascribed merely to the fact that the patient has only a small quantity of reagin in her blood.

In all probability and in view of her continuous treatment since November 1936, she is not infectious. If she becomes pregnant and continues treatment throughout the course of her pregnancy, there is nearly absolute certainty that the child would be normal, healthy and nonsyphilitic.

The management of a case such as this was described in detail in an article by Joseph Earle Moore and Paul Padgett entitled *The Problem of Seroresistant Syphilis*, in *THE JOURNAL* January 8, 1938, page 96.

OPERATIONS FOR CONGENITAL DISLOCATION OF HIPS

To the Editor:—A woman, aged 26, with a bilateral congenital dislocation of the hips, was advised when she was 9 that nothing could be done for her. Have there been any recent surgical procedures which have been used successfully in these cases?

M.D., New York.

ANSWER.—Roentgenograms of the pelvis help materially in determining the appropriate surgical procedure in an individual case. The two chief types of operations that are performed for this condition are (1) the so-called "shelving operations" (which should be "roofing operations") and (2) the so-called bifurcation operations.

Koenig performed a shelf operation for congenital dislocation of the hip in 1891. Ferguson in 1904 and Clarke in 1909 performed similar operations. Albee suggested a bone wedge graft remodeling operation. Maclaure in 1922 reported the use of osteoperiosteal grafts in forming a shelf. Dickson in 1924 reported five cases in which a wedge of bone from the iliac

crest was used to hold the shelf in position. Lance of France reported a similar procedure, with the use of osteoperiosteal grafts to hold the shelf in position. Gill reported a similar procedure. Hey Groves described four different operations to accomplish the same purpose. Spitzzy suggested a shelf operation in which the shelf was made from a massive graft from the ilium and the head was held in position by another graft driven into the acetabulum. Soutter fashioned a shelf out of a piece of bone taken from the anterior surface of the neck, trochanter and shaft of the femur, wedging it into the ilium above the head.

In the bifurcation operation usually spoken of as the Lorenz operation (in reality von Baeyer described it earlier) an oblique osteotomy of the femur is performed with the upper end of the cut at the level of the acetabulum. The distal end of the bone is placed in the acetabulum, forming a Y. This operation is used especially in old, irreducible bilateral cases; it restores the anteroposterior equilibrium of the body, thus overcoming lordosis and eliminating pain.

In the bifurcation operation, Putti advises that the lesser trochanter be attached to the proximal fragments.

A good description of the bifurcation operation is given by Rudolph S. Reich in the *Journal of Bone and Joint Surgery* 7:598 (July) 1925.

DYSMENORRHEA

To the Editor:—A woman, aged 30, married eight years, a nullipara, began menstruation at the age of 14 and has continued regularly every twenty-eight to thirty days. The flow has been moderate. Severe dysmenorrhea has been present always, the pain starting an hour or two before the flow and persisting severely for about twenty-four hours. Relief is obtained only with hypodermic injections of morphine or pantopon. Oral medication has been ineffectual. The pain seems fully as severe as the pain of gallstone colic. Up to six months ago the agonizing pain was the only disorder. For the last six months, however, the patient has been very nervous and feels weak for about a week before and a week after menstruation. The temperature has often been from 99 to 99.6 F. during this time. Twice she fainted about a day after the onset of the menses, and the feeling of impending syncope has become so constant that I keep her supplied with strychnine. The amount and duration of the flow have not changed. About five years ago a dilation and curettage was performed, with no change in symptoms. About ten years ago a nontoxic adenoma of the thyroid was removed. Physical examination is negative throughout and no abnormalities of the pelvic organs were noted. The patient is entirely well for the two weeks between periods. She does not appear to be "nervous" or afraid of pain. The blood, urine, blood chemistry determinations and electrocardiogram are normal. The basal metabolism is minus 20, though the pulse is about 75 to 80. Do you think that any glandular medication is indicated and, if so, what? (I did try antuitrin-S, but it made her "weak and trembly," so I discontinued it.) Would not a surgical menopause be justified, in view of the years of suffering that seem to portend? Is there any danger in using x-rays to induce the menopause? I would appreciate your advice as to specific directions in treatment.

M.D., N. Y.

ANSWER.—The medication of severe dysmenorrhea is often unsatisfactory. This is due to the fact that the cause of painful menstruation is often difficult to determine. One should always consider the possibility of endometriosis in patients who have had symptoms of long standing. Allergic conditions are responsible for dysmenorrhea in some cases (Schwarz, Otto, and Smith, Dudley: *Essential Dysmenorrhea and Allergy*, *Am. J. Obst. & Gynec.* 33:331 [Feb.] 1937).

The only endocrine preparation which has been found to be of value in some cases of dysmenorrhea is progestin. This will cause the relaxation of the uterine musculature so that patients may be benefited in whom excessive uterine motility is the cause of the dysmenorrhea. Progesterone can be given in doses of 1 rabbit unit on each of three days prior to the onset of menstruation. It is sometimes advisable to give 2 rabbit units the days the menses begin. Of course, this therapy will have to be repeated each month in order that the patient may continue to obtain relief by means of the medication. Antuitrin-S is probably of no value for this purpose.

It is almost never justifiable to consider either a surgical or an irradiation menopause for dysmenorrhea in a woman of 30. The sudden climacteric may prove to be stormy. Furthermore, few women reconcile themselves to the premature termination of their reproductive period. Possibly parasympathectomy rather than an artificial menopause should be considered in stubborn cases that resist all other forms of treatment. There is no great danger in inducing the premature menopause by x-rays when this measure is indicated. The surgical approach, however, is to be performed in young women because a hysterectomy can be done and the ovaries and tubes can be left behind, thereby preventing the immediate onset of the climacteric. The surgical approach likewise would rule out the possibility of a pathologic condition which might be responsible for the severe dysmenorrhea.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 25, page 2174.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held at various centers of the United States and Canada, Oct. 17. *Final date for filing applications is Sept. 1.* Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Suite 1210, Des Moines, Iowa.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written examination for Group B candidates* will be held in various states of this country and Canada, Nov. 5. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: Washington, D. C., Oct. 8, and New York, Oct. 7. *All applications should be filed immediately and case reports, in duplicate, must be filed not later than sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

California Reciprocity and Endorsement Report

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports fifty-six physicians licensed by reciprocity and thirteen physicians licensed by endorsement from Jan. 3 through March 31, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Arkansas School of Medicine.....	(1920)		Arkansas
Stanford University School of Medicine.....	(1934)		Minnesota
University of Colorado School of Medicine (1933), (1936, 2)			Colorado
Yale University School of Medicine (1921) New York, (1930)			Penna.
George Washington University School of Medicine.....	(1927)		New York

Rhode Island January Examination

Mr. Robert D. Wholey, chief, Division of Examiners, reports the oral, written and practical examination held by the Board of Examiners in Medicine at Providence, Jan. 6-7, 1938. The examination covered twenty subjects and included fifty questions. An average of 80 per cent was required to pass. Seven candidates were examined, all of whom passed. Five physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
State University of Iowa College of Medicine.....	(1934)		91
Boston University School of Medicine.....	(1935)		86
Harvard University Medical School.....	(1936)		87, 89
Long Island College of Medicine.....	(1936)		80
Vanderbilt University School of Medicine.....	(1930)		92
Regia Università degli Studi di Roma. Facoltà di Medicina e Chirurgia.....	(1935)		90

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Georgetown University School of Medicine.....	(1935)		N. B. M. Ex.
University of Maryland School of Medicine and College of Physicians and Surgeons.....			M. Ex.
Boston University School			M. Ex.
University of Nebraska Co			M. Ex.
Syracuse University Colle			M. Ex.

Colorado January Report

Dr. Harvey W. Snyder, secretary, Colorado State Board of Medical Examiners, reports the written examination held at Denver, Jan. 5-7, 1938. The examination covered 8 subjects and included 165 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. Eight physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine.....	(1936)		80
Northwestern University Medical School.....	(1937)		81, 83
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin	(1903)		78
Osteopaths*			75.5, 82

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
College of Medical Evangelists.....	(1936)		Washington
State University of Iowa College of Medicine.....	(1933)		Iowa
Tulane University of Louisiana School of Medicine.....	(1921)		New York
University of Michigan Medical School.....	(1934)		Michigan
Washington University School of Medicine.....	(1932)		Missouri
University of Nebraska College of Medicine.....	(1936, 2)		Nebraska
Columbia Univ. College of Physicians and Surgeons (1913)			Missouri

* Licensed to practice medicine and surgery.

Oregon Reciprocity and Endorsement Report

Dr. Joseph F. Wood, secretary, Oregon State Board of Medical Examiners, reports three physicians licensed by reciprocity and two physicians licensed by endorsement from Feb. 17 through May 6, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
State University of Iowa College of Medicine.....	(1936)		Iowa
University of Nebraska College of Medicine.....	(1927)		Nebraska
University of Pennsylvania School of Medicine.....	(1927)		S. Dakota

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
University of Michigan Medical School.....	(1932)		N. B. M. Ex.
University of Oregon Medical School.....	(1934)		N. B. M. Ex.

Georgia Reciprocity and Endorsement Report

Mr. R. C. Coleman, joint-secretary, State Examining Boards, reports nine physicians licensed by reciprocity and one physician licensed by endorsement from Jan. 1 through June 15, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Howard University College of Medicine.....	(1935)		Virginia
University of Louisville School of Medicine.....	(1936)		Kentucky
Tulane University of Louisiana School of Medicine.....	(1931)		N. Carolina
Western Reserve University School of Medicine.....	(1933)		Ohio
Jefferson Medical College of Philadelphia.....	(1926)		Ohio
Medical College of the State of South Carolina.....	(1935)		S. Carolina

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Harvard University Medical School.....	(1933)		N. B. M. Ex.

Book Notices

New and Nonofficial Remedies, 1938, Containing Descriptions of the Articles Which Stand Accepted by the Council on Pharmacy and Chemistry of the American Medical Association on January 1, 1938. Cloth. Price, \$1.50. Pp. 590. Chicago: American Medical Association, 1938.

Perhaps the most noteworthy feature of the 1938 edition of *New and Nonofficial Remedies* is the revision of the chapter on vitamin preparations to bring to date the valuable list of "allowable claims." As knowledge increases with the isolation of the crystalline vitamins and experimentation with them, greater simplification may be expected. One notes the addition in this volume of riboflavin (vitamin B₂ or G), and it is understood that thiamin chloride (vitamin B₁) will be in the next edition.

Other new substances described in this volume are sulfanilamide and protamine zinc insulin, with the accepted brands. The proved value of these new additions to the physician's armamentarium bids fair to make the past year a milestone in therapeutic progress. The Council is to be congratulated on the promptness with which it evaluated these drugs and established standards for their adequate control. From the first the Council warned against using sulfanilamide in untried combinations. The sad tragedy of the deaths from the rashly introduced Elixir of Sulfanilamide-Massengill starkly emphasizes the value of such a body as the Council to the medical profession and the pharmaceutical manufacturers as well as to the public. Of course this potential value cannot become effective as long as those concerned refuse to follow the Council in the use of new remedies.

Other noteworthy new drugs which appear in *New and Nonofficial Remedies 1938* are avertin with amylene hydrate, vinethine, pontocaine hydrochloride, basal, general and local anesthetics respectively; mandelic acid, a new urinary antiseptic; novatropine and syntropan, synthetic mydriatics.

Among the products omitted from this year's volume, of which there is about the usual number, either for conflict with the rules or as being off the market, are all the creosote and guaiacol preparations that have stood accepted for so many years. In a careful revaluation of these preparations extending over two or three years the Council came to the conclusion that they should be relegated to the therapeutic scrap heap, at the same time announcing that the matter would be reconsidered if and when interested manufacturers could present new and convincing evidence.

No review of an annual volume of *New and Nonofficial Remedies* would be complete without a word of praise and appreciation for the Council, the tireless and freely given labor of whose members makes possible this valuable manual of therapeutic progress.

Bienengift als Heilmittel. Von Dr. Robert Schwab, Innere Abteilung des Julius-Hospitals in Würzburg. Boards. Price, 2.40 marks. Pp. 48, with one illustration. Leipzig: Georg Thieme, 1938.

Bee venom is recommended in the warfare against rheumatism, a disease so common as to exceed even tuberculosis (12 per cent as against 10 per cent in 1931). This remedy, known to popular medicine for thousands of years, has only of late been employed by physicians and, it seems, with a certain degree of success. The original method of employment was the bee sting as a result of the ancient observation that bee keepers became immune not only to bee stings but also to rheumatism. It seems, on the other hand, that the patient with rheumatism is a priori immune against the bee stings (primary negative phase). It is only after several stings that the local reactions occur (secondary positive phase), which is followed by a secondary negative phase, and it is during this that it is claimed the healing occurs. The suggestion is advanced that rheumatism, which is an allergic reaction, may be favorably influenced by the induction in this manner of a refractory phase, which may be of value also in other allergic conditions, such as hay fever. Bee poison has been produced in relatively pure form and made available in dilutions for administration by injection and of late also in ointment form. This salve, the exact composition of which is not given, is said to contain minute crystals which on inunction damage the skin sufficiently to permit percutaneous absorption. The penetration is improved by means of iontophoresis and still more

by the additional employment of histamine. One naturally wonders whether this combination of bee poison with histamine, iontophoresis, which in itself is claimed to be useful in rheumatism, may not be an admission that the results secured by the bee poison alone are not entirely satisfactory.

The Diagnosis and Treatment of Sexual Disorders in the Male and Female Including Sterility and Impotence. By Max Huhner, M.D., Attending Genitourinary Surgeon, Bellerue Hospital, Out-Patient Department, New York City. Cloth. Price, \$5. Pp. 490, with illustrations. Philadelphia: F. A. Davis Company, 1937.

The book called "Disorders of the Sexual Function," first published by this author in 1917, was reprinted eleven times between 1917 and 1921. The second revised edition was reprinted ten times up to 1929, when the third edition was published. The present work is not a revision but an entirely new work, largely because of the great discoveries that have been made in the field of sexual disorders during the past twenty-five years. Today these disorders lie midway between pure neurology and psychiatry and pure genito-urinary pathology. In the present book the entire subject of impotence has been rewritten. There are discussions of the Steinach operation, the influence of the endocrine system, the Freudian point of view and similar subjects. There is also a new discussion on masturbation and of sterility and an abundant bibliography. Several contributions made by the author to various systems of medicine have also been developed into portions of this book. The volume is organized to include sterility, impotence, masturbation, pollutions, priapism, continence, sexual neuroses, enuresis, frigidity and many similar subjects. The book is based on a large practical experience and on a conservative attitude toward unestablished theories. It is among the most useful for the average physician who is occasionally concerned with such cases.

Practical Procedures. Edited by Sir Humphry Rolleston, Bt., G.C.V.O., M.D., and Alan A. Moncrieff, M.D., F.R.C.P. With a preface by Sir David Wiltke, O.B.E., M.D., M.Ch. Published on behalf of The Practitioner. Cloth. Price, 10s. 6d. Pp. 293, with 66 illustrations. London: Eyre and Spottiswoode, Ltd., 1938.

This volume of the Practitioner handbook series is decidedly welcome, as it covers the borderland between medicine and surgery in a territory in which the well trained practitioner finds his most interesting and fruitful field. The aim of this book is to deal with practical procedures in a simple but detailed manner by experts who have experienced the pitfalls. It includes such items as plaster-of-paris technic, administration of fluids by injection, technic for blood transfusion, pleural aspiration, use of the catheter, injection treatment, local anesthesia and various topics of clinical laboratory diagnosis. It should be of real help to many a physician in need of such practical information and most especially to hospital interns and residents. Indeed, no hospital library should be without this little volume.

The Carnegie Foundation for the Advancement of Teaching. Thirty-Second Annual Report. Paper. Gratis. Pp. 202. New York City, 1937.

In the thirty-second annual report of the Carnegie Foundation, President Walter A. Jessup discusses the intensive competition now carried on between colleges for the recruiting of students. "We are familiar with the 'inducements' offered to promising athletes, but we may be astonished by the fact that drum majors and tuba players now find themselves possessed of special talents with a marketable value in the college field. Jobs and scholarships are dangled before the eyes of impecunious high school pupils. Fraternities and sororities vie in recruiting students who can pay their bills and bring glory (in press notices) to a chapter. The evil thread which runs through the fabric of recruitment devices is the attempt through them to exploit the student."

"Many institutions," continues Dr. Jessup, "today are giving renewed serious consideration to the selection of students adapted to their particular programs. The right selection of students, in accordance with a clear and understood institutional purpose, benefits not only the university or college that employs it but every undergraduate fortunate enough to enjoy its privileges. . . ."

"The president of a small college recently said 'We know that we are accepting students who cannot do our work. We know that we are carrying these students forward to gradua-

tion. In our present situation we are under such pressure that we feel we have no other choice. Our campus morale is affected by numbers and a reduction in attendance is looked upon as a slump—as though the institution were losing ground.”

Dr. Jessup writes “No college can be free from the necessity of competing with other institutions. The means adopted have perforce included some consideration of the relation of the college to the general public, for the typical college, beset on every hand with competition, must vie with its neighbors for public approval. In consequence, it has adopted devices common to other competitive social and economic enterprises. It has changed the nature of its catalogue. It has employed publicity agents. It has pressed its alumni into service as recruiting officers. It has issued neat and none too modest printed matter to attract students. Its ‘follow-up’ system is often very efficient indeed. And it has deemed itself forced to do these things by a feeling that it must struggle if it is to survive and go forward.”

The report contains a description of the purposes and activities of the foundation from its establishment in 1905 by Andrew Carnegie to the present day. It has disbursed more than \$32,769,900 for retiring allowances and widows' pensions in 168 colleges, universities and technical schools in the United States and Canada, for 2,621 individuals comprising 1,752 retired teachers and officers and 869 widows. The foundation has conducted numerous educational inquiries, some of the results of which have been published in twenty-eight bulletins, thirty-two annual reports and twenty-seven miscellaneous publications, comprising altogether some 15,000 printed pages.

Of the institutions which since 1905 have received from the Carnegie Foundation more than \$32,000,000 for retiring allowances and widows' pensions, Harvard University has had more than \$2,690,000, Columbia University \$2,341,000, Yale University \$2,042,000, Cornell University \$1,500,000, the University of Michigan \$1,075,000, the University of California \$927,000, the University of Toronto \$908,000, the University of Wisconsin \$786,000 and Princeton University \$744,800.

Copies of this report and any of the other publications of the foundation now in print may be had without charge on application by mail or in person to the office of the foundation at 522 Fifth Avenue, New York.

Bibliographie der Luftfahrtmedizin: Eine Zusammenstellung von Arbeiten über Luftfahrtmedizin und Grenzgebiete bis Ende 1936. Von Dr. Med. Ingeborg Schmidt, Leiterin der Bücherei und Assistentin am Luftfahrtmedizinischen Forschungsinstitut des Reichsluftfahrtministeriums Berlin. Paper. Price, 14 marks. Pp. 136. Berlin: Julius Springer, 1938.

This small volume in paper cover constitutes a comprehensive and excellent bibliography of aviation medicine, including 1936. Since the World War this newer specialty in medicine has kept abreast of the rapid expansion of aviation throughout the world, and research in the various phases has resulted in a rather heterogeneous literature. The compilation of a bibliography is timely and most serviceable to those interested in further studies of the medical aspects of aviation. The present work is divided into subheads including general considerations, psychophysiology of flight, altitude effects, atmospheric pressure, wind, cold, light and gravitational effects, diseases and injuries peculiar to flying, and the various aspects of hygiene and sanitation of aviation. It is catalogued by authors and lacks a cross subject index. This deficiency is of minor importance and should not keep the book from the reference shelves of flight surgeons and others interested in aviation medicine.

Collected Papers on Tuberculosis. By Sir Robert W. Philip, M.A., M.D., LL.D., Extra Physician to His Majesty the King in Scotland. Cloth. Price, \$7.50. Pp. 460. New York & London: Oxford University Press, 1937.

This volume of twenty-four collected essays and papers on tuberculosis comes from the pen of one whose medical career spans the era of modern knowledge of the disease. In the development of this knowledge and the means of controlling tuberculosis, the author has taken a prominent part by his pioneer work in the establishment of clinics and dispensaries for the study of the disease, methods of case finding, agitation for compulsory notification of active cases, and tuberculinotherapy. A graduate of medicine in the year that Koch announced the discovery of the causative organism of tuberculosis, the author became interested in the subject because

of a demonstration of the bacilli while working in Vienna in 1882-1883. Fired with enthusiasm by the new vistas thus opened, he returned to Edinburgh to meet apathy and indifference. “Everybody knew everything that was to be known about tuberculosis. It was a worked-out subject, and the outlook on prevention and treatment was correspondingly hopeless.” A desire to establish a center for the collection, grouping and observation of cases at various stages of the disease led to the establishment in 1887 of the first tuberculosis clinic, the Victoria Hospital for Consumption. His first report on the prevention and cure of the disease before the British Medical Association in 1896 was deemed of so little significance that mention of it was omitted from the printed transactions. In 1890 he advocated compulsory notification of active cases; a fundamental step in the control of the disease which was not enacted into law until 1912. In 1928 Professor Philip was awarded the Trudeau Medal of the National Tuberculosis Association, the first foreigner to be so honored. To those interested in the subject of tuberculosis, the essays provide a delightfully written historical retrospect.

Weiteres über Geschwülste. Von K. A. Helberg. Paper. Price, 2.50 Danish kroner. Pp. 56, with 19 illustrations. Copenhagen: Levin & Munksgaard; Leipzig: Georg Thieme, 1938.

This booklet contains six brief discussions on certain points, mainly morphologic, connected with basal cell carcinoma of the skin; nevi, nevocarcinoma, carcinoids; hemangioma, telangiectatic granuloma and Kaposi's sarcoma; the thyroid; lymphogranulomatosis, and the cellular and nuclear dimensions in carcinoma. Clinical diagnosis and treatment are not considered.

Pseudocyesis. By George Davis Bivin, Ph.D., and M. Pauline Klinger, M.A. A Monograph of the George Davis Bivin Foundation. Cloth. Price, \$4. Pp. 265, with 5 illustrations. Bloomington, Indiana: The Principia Press, Inc., 1937.

Neither of the authors of this book is a physician. Bivin was a psychologist interested primarily in abnormal psychology who established the Medical-Psychology Research Institute, now called the George Davis Bivin Foundation, Inc., associated with the Indiana University. Apparently spurious pregnancy has been recognized since the earliest times, and it is reported that the hippocratic volumes showed at least twelve cases around 300 B. C. The famous cases include, for example, the one of Mary Tudor, queen of England. The authors have collected records of cases throughout the world, many of them not only interesting scientifically but also having extraordinary elements of humor. It is interesting that the work should have been prepared without medical consultation, since the aspects of these cases are as much medical as psychologic. In the concluding pages the evidence of similar cases among cats, cows and dogs is offered.

Malnutrition: The Medical Octopus. By John Preston Sutherland, M.D., Sc.D. Cloth. Price, \$3. Pp. 368. Boston: Meador Publishing Company, 1937.

This book is not worth the serious consideration of the medical profession. The author explains that it was written in answer to the questions “Why do I eat?” and “What shall I eat?” The explanation covers 368 pages. One of these pages, near the end of the book, contains a summary of some of the inaccuracies and curious bits of misinformation, which in one way or another the book provides in abundance, under the heading “Fundamental Prohibitions.” These include “Do not eat white flour in any form whatever” and “do not eat cane or beet sugar in or on anything.” The author specifically admonishes the reader not to eat cream of wheat, polished rice, cakes, pies, puddings, ice cream, pared potatoes in any form, or the majority of cereal breakfast foods. These blanket prohibitions are just as ridiculous as the author's belief that cow's milk is not entirely suitable as a food for human beings and that “its free use probably is more injurious than beneficial to mankind.” The jacket of the book contains laudatory comments by Dr. Percy R. Howe, Sir W. Arbuthnot Lane, Senator Royal S. Copeland and others. The comments do not indicate whether these individuals eat their potatoes with the skins on or whether they believe with the author that nuts may be taken freely and in any variety.

Essentials of Prescription Writing. By Cary Eggleston, M.D., Assistant Professor of Clinical Medicine, Cornell University Medical College, New York City. Sixth edition. Cloth. Price, \$1.50. Pp. 155. Philadelphia & London: W. B. Saunders Company, 1938.

In his preface the author speaks of the revision having become necessary by the eleventh edition of the U. S. Pharmacopeia and the sixth edition of the National Formulary. The author has seen fit to omit iso-alcoholic elixir, which by many is considered an important addition to the group of vehicles. Syrup of cherry, which is official in the National Formulary, is spoken of as being nonofficial. Such and similar minor inaccuracies are rather regrettable in a book the avowed purpose of which is to teach correct prescription writing. Otherwise the booklet meets the requirements well. It stresses prescription writing in Latin.

Die tierischen Parasiten des Menschen. Von Dr. Walter Stempel, Hon.-Professor der Zoologie, vergleichenden Anatomie und vergleichenden Physiologie an der Westfälischen Wilhelms-Universität zu Münster i. W. Paper. Price, 12 marks. Pp. 226, with 219 illustrations. Jena: Gustav Fischer, 1938.

Because there has existed in the German language no short and practical publication on the animal parasites, the author has prepared this volume. It is intended as a ready reference for the physician rather than the parasitologist, containing brief paragraphs about the various animal parasites that infest man. The less significant forms are described in fine print, while those of greater medical importance are printed in larger type, together with a certain amount of clinical material. The book is divided into six parts. The first part, of eleven pages, discusses parasitism in general; the main part, of nearly 200 pages, takes up the protozoa, the worms and the arthropods; the third part presents an index to parasites infesting the different parts of the body, such as the muscle, the blood, the skin and the intestinal canal. The remainder of the book is devoted to a chronologic list of literature on parasitology, to a table of corrections for errors that appear in the text, and to the alphabetical index.

Surgical Pathology of the Diseases of the Neck. By Arthur E. Hertzler, M.D., Surgeon to the Agnes Hertzler Memorial Hospital, Halstead, Kansas. Hertzler's Monographs on Surgical Pathology. Cloth. Price, \$5. Pp. 237, with 208 illustrations. Philadelphia, Montreal & London: J. B. Lippincott Company, 1937.

This is a fairly brief monograph reflecting the author's experience with various diseases of the neck. He expresses himself freely on controversial subjects but not always with the greatest clarity. Apparently most of the information contained in this monograph is from the author's personal experience and includes chapters on Hodgkin's disease, lymphosarcomas and rare primary tumors of the neck. There is a section of inflammatory lesions of the neck which is too brief and skimpy on such afflictions as actinomycosis. On the difficult problem of metastases to the lymph nodes of the neck, no mention is made of tumor grading according to histology as a guide to further therapy. The author does deplore the failure to make biopsies of lesions treated with irradiation and points to the pitfalls to which this may lead. As can be expected, most of the material presented is such as is seen by the surgeon clinically and grossly rather than actual pathologic tissue after it has left the body.

Manual of Human Dissection. By Edwin M. Shearer, Ph.D., Associate Professor of Anatomy, New York University College of Medicine, New York. Cloth. Price, \$4.25. Pp. 321, with 79 illustrations by the author. Philadelphia: P. Blakiston's Son & Co., Inc., 1937.

This is a good laboratory guide for dissection. It is good because it does not include either a textbook or an atlas and because it leaves out structures of small importance. The time allotted dissection to the curriculum of the ordinary school of medicine in America is less than it once was. It permits thorough dissection and study of only some structures. The student needs guidance in picking out those most worthy of thorough study from the point of view of clinical medicine. This book gives such guidance well and sufficiently. It can be recommended as better than the longer laboratory guides formerly used when the student had a longer time for dissection. The binding is excellent and will stand up in dissecting rooms.

On Deficiency of A Vitamin and Visual Dysadaptation. II. By C. Edmund and Sr. Clemmesen. Paper. Price, 3 kroner. Pp. 52, with 5 illustrations. Copenhagen: Levin & Munksgaard; London: Oxford University Press, 1937.

By the power of distinction method, in which the discriminability of letters of different degrees of contrast is determined at various illuminations, Edmund and Clemmesen examined the adaptation faculty (aptation) of the retina in a group of pregnant medical patients and concluded that the number of cases of dysadaptation in this class of patients had decreased during the past year, probably because of the popular agitation concerning vitamins stirred up by the press and as a result of the vitaminization of margarin. A nine months investigation of a selected group of prisoners in the state prison in Nyborg was done by the same method to determine the adequacy or inadequacy of the prison diet with respect to vitamin A. It was concluded that a diet containing 1,374 international units of vitamin A daily is adequate to obliterate seasonal oscillations in the power of distinction. The ordinary prison diet (1,225 units daily) is insufficient for this purpose and should be supplemented with sweet milk, although rarely does actual dysadaptation occur with this diet.

Pavlov and His School: The Theory of Conditioned Reflexes. By Professor Y. P. Frolov, M.D., Member of the All Union Institute of Experimental Medicine, Moscow. Translated from the Russian by C. P. Dutt, B.A. Cloth. Price, \$4. Pp. 291, with 26 illustrations. New York: Oxford University Press, 1937.

Biographic information, a concise account of the theory of conditioned reflexes, a record of the work of the predecessors of Pavlov on which his studies were based and a description of his methods of work and of his school are offered by this volume. The author, who was a student of Pavlov, first wrote the work in Russian, and the translation is by C. P. Dutt. Out of the years of his study and research, Pavlov summed up the basic qualities of mind indispensable to a scientist. As these were finally formulated they were published posthumously and are certainly worthy of repetition:

What is it that I would wish the young men and women of my country who have dedicated themselves to science?

First of all, consistency. Of this very important condition of fruitful scientific work I can never speak without emotion. Consistency, consistency and again consistency. From the very beginning of your work train yourself to strict consistency in the acquirement of knowledge.

Learn the A B C of science before you attempt to scale its peaks. Never embark on what comes after without having mastered what goes before. Never try to cover up the gaps in your knowledge, even by the boldest guesses and hypotheses. Such a bubble may delight your eyes by its play of colors, but it will inevitably burst and you will be left with nothing but confusion.

Train yourself to reserve and patience. Learn to do the heavy work that science involves. Study, compare, accumulate facts. Be the wing of a bird never so perfect, it would never bear her aloft without the support of the air. Facts are the scientist's air, without which he would never be able to fly. Without facts, your theories are labor in vain.

But in studying, experimenting and observing try not to remain at the surface of the facts. Do not turn yourself into a museum custodian of facts. Try to penetrate into the secret of their origin. Steadfastly seek the laws that govern them.

The second thing is modesty. Never think that you already know everything. And however high the esteem in which you are held, always have the courage to say to yourself "I am ignorant."

Do not allow pride to take possession of you. It will cause you to be obstinate when you should be conciliatory. It will cause you to reject useful advice and friendly help. It will prevent you from taking an objective view.

In the collective which I have to guide, everything depends on the atmosphere. We are all harnessed to a common cause and each of us helps it forward to the extent of his strength and possibility. With us it is often impossible to distinguish what is "mine" and what is "yours." But our common cause only gains thereby.

The third thing is passion. Remember that science demands a man's whole life. And even if you had two lives, it would not be enough. Science demands from man great intensity and deep passion. Be passionate in your work and searchings.

Our fatherland is opening wide prospects before scientists and—it must be owned—science is being fostered in our country with the utmost lavishness.

What should I say of the position of the young scientist in our country? Is not everything quite clear here? Much is given him, but much is asked of him. For youth, as for us, it is a matter of honor to justify the great trust that our fatherland puts in science.

Among the most interesting of the chapters is that dealing with Pavlov at home. He had a fixed routine of life. He was left handed. His favorite outdoor game was skittles, indoor game solitaire. He relaxed by looking at his collection of pictures or by listening to his favorite airs on the phonograph. He was particularly fond of the writings of Goethe and Shake-

speare, but he spent little time reading outside his field of science. He slept from 1:30 a. m. to 7:30 a. m. as a rule. The final plate in the book is a picture of the great master on the platform at the fifteenth International Congress of Physiologists in August 1935.

Die Operation in der Sprechstunde. Von Dr. Richard Goldhahn, Chefarzt des Kreiskrankenhauses in Liegnitz. Boards. Price, 6.80 marks. Pp. 181, with 68 illustrations. Leipzig: Georg Thieme, 1938.

This small volume contains a great deal of valuable information and guidance in the matter of minor surgical procedures. It would seem, however, that it would more truly be an office surgery if the descriptions of extraction of teeth, tracheotomy and suboccipital puncture had been omitted. The author shows a broad knowledge of the surgical literature, to which frequent references are made. The format is excellent; the illustrations are only average.

Meditatio Medici: A Doctor's Philosophy of Life. By W. Cecil Bosanquet, D.M., F.R.C.P. Cloth. Price, 7s. 6d. Pp. 162. Aldershot: Gale & Polden, Limited, 1937.

On the basis that every man should be his own philosopher, a distinguished physician here presents his own philosophy of life. He comes to the conclusion that the essence of civilization is the equalization of conditions for all members of a community so that those less favored by nature are artificially protected and preserved, and that western civilization tends in many ways to encourage and promote mediocrity and inefficiency rather than strength and ability. As a result, he sees only gradual decline of human vigor among European races. He is convinced that the hope of gaining something for himself and his family is man's chief spur to human action and that any interference with this spur will bring about stagnation. Stagnation invariably involves degeneration. A final paragraph sums up Bosanquet's concept of a well ordered evolution:

Perhaps, then, we may congratulate ourselves on a remnant of sinfulness in our own generation, in whom the love of combat is not quite extinct; for whom absolute social equality for all is not yet established; who have still some prizes to struggle for and some difficulties to overcome. We may even hope that the same opportunities for the display of energy may be afforded to many generations yet of those who come after us. The desire for rest and repose is natural and right, but only after labor. We can all echo the prayer for peace and good fellowship with neighboring nations; but nature knows nothing of peace, only endless conflict and rivalry among living creatures, and her laws are binding on mankind as well as on lower forms. The saying of the old Greek philosopher Heraclitus that "Conflict is the Father of all things" represents the creed of the evolutionist that only by struggle and rivalry—not necessarily by arms and bloodshed, but by emulation at any rate in the arts of commerce, industry and invention—is that progress possible to mankind which is the sole alternative to stagnation, degeneration and decay.

The Evolution of Chronic Rheumatism with Treatment to Correspond. The Preventive Clinic as a First Line of Defence. By R. Fortescue Fox, M.D., F.R.C.P. Founded on a lecture delivered at Margate, at the Congress of The Royal Institute of Public Health and The Institute of Hygiene, May, 1937. Paper. Price, 2s. 6d. Pp. 26, with 5 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

This little pamphlet by one of the most eminent English students of rheumatism enters a brief plea for a broad view on the etiology and treatment of rheumatic diseases. In it appears a brief discussion of certain phases of physical therapy, especially with regard to the advantages of warmth in treatment and the serious dangers of chill and cold. While in no sense a comprehensive report in the field, it reflects some of its distinguished author's views.

Dr. Bodo Otto and the Medical Background of the American Revolution. By James E. Gibson. Cloth. Price, \$4. Pp. 345, with illustrations. Springfield, Illinois, & Baltimore: Charles C. Thomas, 1937.

Dr. Bodo Otto and his family arrived in Philadelphia in 1755. In a German newspaper, two months after the arrival, appeared an announcement as to his qualifications in medicine and offering his services to those who were ill. Dr. Bodo Otto served in the hospitals in connection with the Revolutionary War during the years 1776-1782, between the age of 65 and 72 years. His sons also served during the war, one of them in the double capacity of commander of a New Jersey regiment and as a physician. Around his work and his career, James E. Gibson has drawn a picture of medical service during the Revolutionary War, illustrated with original documents and recounting again the services of Morgan, Benjamin Rush, Shippen and others. Dr. Bodo Otto was in command of the hospital in Philadelphia

located on the square bounded by Eleventh, Twelfth, Spruce and Pine streets. One chapter deals with the famous controversy between Benjamin Rush and Shippen and provides a record of Shippen's trial and acquittal. Dr. Bodo Otto aligned himself with Shippen as against Rush and Morgan. At the end of his six years of service he found himself without funds, and he accepted an offer from the Congress of the United States of two years' full pay in lieu of half pay for the rest of his life as a means of settling the obligation of the government to him. There is available a letter which he addressed to the Congress indicating that he had lost his medicine chests and all his utensils during the war. Congress never discharged the obligation to him and the records indicate that Haym Solomon of Philadelphia extended personal assistance to him in lieu of the money owed to him by the government, as he did to many other needy governmental officials. To all physicians interested in the medical side of the Revolutionary War, this volume will be a most interesting contribution.

La atelectasia pulmonar. Por Julio Palacio, profesor adjunto de clínica médica de la Facultad de medicina, y Egidio S. Mazzel, jefe de trabajos prácticos de la Cátedra del Prof. M. R. Castex. Prefacio del Prof. W. Unverricht. Biblioteca argentina de medicina interna, Volumen II. Paper. Pp. 159, with 76 illustrations. Buenos Aires: Aniceto Lopez, 1937.

Pulmonary atelectasis is of great practical importance and has been the subject of many clinical and experimental studies during the last few years. Drs. Palacio and Mazzei have published several articles about the disease. The present book is a complete study of pulmonary atelectasis, especially from a clinical and radiologic point of view. The first chapter deals with the nature of the disease and the evaluation of its knowledge. The second, third and fourth chapters deal with the mechanical and nervous theories of the pathogenesis of pulmonary atelectasis, as well as with the pathologic anatomy, symptoms, diagnosis and clinical forms of the disease. In the remaining chapters the different forms of atelectasis are studied; that is, atelectasis in tuberculosis, collapse therapy, suppuration and cancer of the lung, acute pneumonopathies, hemoptysis, bronchiectasis, spontaneous pneumothorax and postoperative atelectasis. The book is a contribution of value to medical literature. It has many illustrations, some of which are in color, and ends with thirty pages of bibliography.

Practical Chiropody. By E. G. V. Runtig, F.I.S.Ch. Fifth edition. Cloth. Price, \$3. Pp. 200, with illustrations. St. Louis: C. V. Mosby Company, 1937.

This small book discusses inflammatory lesions of the foot, verruca, and lesions of the nails, joints and skin. There are chapters on pads and plaster, therapeutic preparations and compounds, and instruments. It appears to be a satisfactory monograph on the subject of practical chiropody which can be recommended to the chiropodist and others who are interested in this subject. The illustrations are simple and instructive. The author is to be commended for keeping to the subject and not wandering over the human anatomy as has been done by others. He emphasizes the importance of good records.

J. B. Murphy, Stormy Petrel of Surgery. By Loyal Davis, M.D., M.S., Ph.D., Professor of Surgery and Chairman of the Division of Surgery in Northwestern University. Cloth. Price, \$3. Pp. 311, with portrait. New York: G. P. Putnam's Sons, 1938.

More than twenty years has now elapsed since the death of Dr. J. B. Murphy, aptly subtitled in the book by Loyal Davis as the "stormy petrel of surgery." To the rapidly growing body of physicians graduated since 1916, Murphy's controversial but vital figure has emerged in countless tales from the lips of their elders. Dr. Davis, who occupies the chair of surgery at Northwestern University Medical School, held at one time by Murphy, has presented a fascinating account of the manifold activities of probably the best known American surgeon of his age. Constantly in hot water because of the publicity accorded to him (some of it apparently unsought), Murphy's unquestioned ability achieved a professional reputation both in this country and abroad equaled by few and surpassed by none. In general, the sources utilized by Davis were favorable to Murphy in most of his controversies. To this extent, therefore, the biography constitutes an apologia; but in

portions of the book, especially at the end, it is indicated that a substantial basis for at least some of the criticisms of Murphy may not have been wholly lacking. The admiration accorded Murphy as well as the opposition he received is admirably illustrated in the book. Certainly Murphy's successive professorship of surgery in Rush Medical College and in Northwestern University Medical School and his election to the presidency of the American Medical Association constitute ample evidence that, whatever Murphy's personal genius for creating virulent opposition, his ability was far out of the ordinary. The historical importance is reflected in the entire gamut of biography—the obscure origin and rapid rise of the "hero", development of antiseptics and asepsis, the Murphy button, the Haymarket riot, the shooting and care of Theodore Roosevelt, and many other general and medical historical events.

Milk Control. Governmental Regulation of the Dairy Industry in the United States. Prepared by the American Municipal Association. Publication No. 57. Paper. Price, 75 cents. Pp. 49. Chicago, Illinois: Public Administration Service, 1937.

The American Municipal Association in the present pamphlet provides a brief account of some of the activities of federal and local agencies with respect to the regulation of the dairy industry in the United States. In the appendixes there are provided the milk ordinance of the United States Public Health Service and brief abstracts of several other items of interest to those concerned with the public health aspects of milk.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Coroners: Right of Minnesota Coroner to Exhume Body for Inquest.—The deceased died under circumstances indicating that her death was due to violence. A partial autopsy was performed and her body was then buried. The contents of her stomach, removed at the autopsy, were analyzed and the report filed about two weeks after the body had been buried showed the presence of strychnine. About a month after the death, the coroner determined to have a further autopsy made and to hold an inquest. He therefore ordered the exhumation of the body and its production at the inquest. The plaintiff, the surviving spouse, thereupon sought to enjoin the coroner and his assistant from holding the inquest and autopsy. The district court, Dakota County, however, after issuing a temporary restraining order, vacated that order. The plaintiff then appealed to the Supreme Court of Minnesota.

The precise question here presented, said the Supreme Court, is whether or not a coroner has the legal right to exhume a body for the purpose of holding an inquest. Mason's Minnesota Statutes, 1927, section 949, sets forth the oath the coroner must administer to the jurors "in view of the dead body":

"When the jurors appear, the coroner shall call their names, and then, in view of the dead body, administer to them the following oath: 'You do swear that you will diligently inquire, and due presentment make on behalf of the state of Minnesota, when, how, and by what means the person whose body lies before you did come to his death.'"

Section 951 lays down the oath required of witnesses:

You do solemnly swear that the evidence you shall give to this inquest concerning the death of the person lying before you dead shall be the whole truth.

Section 953, relating to the form of the inquisition to be returned by the jury provides:

The jury, upon inspection of the dead body, and after hearing the testimony and making the needful inquiries, shall draw up and deliver to the coroner the inquisition.

No claim is made, said the Supreme Court, that the coroner did not have authority to hold an inquest in this case. It was undisputed that the decedent was supposed to have come to her death by violence. In authorizing a coroner to hold an inquest on a person supposed to have come to his death by violence, the legislature must have recognized that facts leading to a suspicion or appearance of death by violence might not become evident until after the burial of the body. In

requiring the presence of the body at the inquest, the statutes impliedly at least give the coroner authority to exhume the body on which the inquest is to be held. Those statutes do not require the coroner to secure a court order authorizing exhumation. As the time element for exhumation may be of the utmost importance in such proceedings, and delay resulting from litigation, because of the processes of decomposition, might thwart the very purpose for which the exhumation was sought, such authorization for summary action by the coroner seemed to the court to be best.

We do not mean, said the Supreme Court, to hold that coroners may exhume bodies indiscriminately, even for the purpose of holding an inquest. The passage of time or other factors might destroy the evidences of the cause of death so that an inquest would not accomplish its purpose; or sufficient cause for holding an inquest might not appear; or considerations of public health and welfare might make it inadvisable to permit the exhumation of a dead body. In such cases, or in any other case in which a proper showing is made, an injunction to prevent exhumation should and undoubtedly would be issued.

The judgment of the court below vacating its temporary restraining order was affirmed by the Supreme Court.—*Sejrup v. Shepard (Minn.)*, 275 N. W. 687.

Malpractice: Bad Result Raised no Presumption of Negligence.—The plaintiff sued Dr. Parker and another physician for malpractice because of a burn allegedly resulting from x-ray treatments prescribed by Dr. Parker. He alleged that he consulted Dr. Parker relative to a tumor in the skin (keloid) behind his right ear and that Dr. Parker directed him to go to a Miss Sykes, whom the plaintiff alleged was an agent of Dr. Parker, in the Pittman Hospital, for x-ray treatments. He had had a growth at the site of the present growth many years before and had had it surgically removed, which left a scar, but it did not "open and close up" until after the x-ray treatment. The plaintiff presented no evidence to show negligence in the administration of the treatment. A physician called by the plaintiff stated that the plaintiff consulted him after the x-ray treatment and then had an "ulcer mastoid" back of his ear, which the witness considered chronic. At the conclusion of the plaintiff's testimony, the court entered a judgment for the defendants and he appealed to the Supreme Court of North Carolina.

The general rule is, said the Supreme Court, that in malpractice actions no presumption of negligence arises from an error of judgment in the diagnosis or the treatment prescribed by a physician, or in failure to effect a remedy or accomplish as good results as some one else might have done. A physician is neither a warrantor of cures nor an insurer. There was not sufficient evidence, therefore, to take the case to the jury. Taking the history of the patient's trouble and the testimony of the physician who was called on his behalf, the court could see no substantial injury, if any at all, caused by the x-ray operator, even granting that she was the agent of the defendant Parker. In the opinion of the court, there was no sufficient probative evidence that the plaintiff's condition was caused by the x-ray treatment complained of. Evidence, to be submitted to the jury, must be more than conjectural or speculative and must be such as will support a finding by the jury that there was negligence. The judgment in favor of the physician was accordingly affirmed.—*Davis v. Pittman (N. C.)*, 194 S. E. 97.

Society Proceedings

COMING MEETINGS

National Medical Association, Hampton, Va., Aug. 15-19. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.
Oregon State Medical Society, Timberline Lodge, Aug. 24-27. Dr. Morris L. Bridgeman, 1020 S.W. Taylor St., Portland, Secretary.
West Virginia State Medical Association, White Sulphur Springs, July 11-13. Mr. Joe W. Savage, Public Library Building, Charleston, Executive Secretary.
Wyoming State Medical Society, Laramie, Aug. 7-9. Dr. M. C. Keith, 156 South Center St., Casper, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

7: 397-440 (May) 1938

Some Thoughts on the Medical Profession. R. S. Hill, Montgomery.—p. 397.

Relation of Public Welfare and Industrial Development to Public Health and Medical Education in Alabama. S. Graves, University.—p. 402.

Treatment of Tetanus: Analysis of Thirty-Six Cases. E. G. Givhan Jr. and T. S. Boozer, Birmingham.—p. 407.

The Undulant Fever Problem: A New and Promising Idea as to Treatment of the Chronic Case. E. Thames, Mobile.—p. 411.

Some Things About the Eye of Interest to the General Physician. F. H. Clements, Birmingham.—p. 416.

American J. Obstetrics and Gynecology, St. Louis

35: 743-924 (May) 1938. Partial Index

Comparative Study of Posterior Pituitary Extract Administered at the Onset of and After Completion of Third Stage of Labor. F. F. Fortin, Chicago.—p. 761.

*Elderly Primiparas: Study of 240 Cases. C. R. Tew, Raleigh, N. C., and K. Kuder, New York.—p. 773.

Pneumococcal Infection of Genital Tract in Women, Especially During Pregnancy and the Puerperium. H. H. Nuckols and A. T. Hertig, Boston.—p. 782.

*Experimental Study of Acidosis and Alkalosis in Labor. W. T. Pride, J. R. Reinberger and D. T. Holland, Memphis, Tenn.—p. 793.

Weight Changes in Pregnancy. P. N. Bray, Duluth, Minn.—p. 802.

Wheat Germ Oil Therapy: III. Rat Experiments, Lactation, Clinical Uses, "Failures" and Effect on Congenital Anomalies. E. Shute, London, Ont., Canada.—p. 810.

Epilepsy and Pregnancy: Review of Literature and Study of Thirty-Seven Cases. A. Baptisti Jr., Baltimore.—p. 818.

Uterine Motility Resulting from Inflammatory Processes in Myometrium, in Absence of Ovarian Hormones. M. W. Laufer and S. R. M. Reynolds, Brooklyn.—p. 825.

Blood Loss in Menorrhagia. Adelaide P. Barer and W. M. Fowler, Iowa City.—p. 839.

Amplification of Fetal Heart Sounds. W. T. Pommerenke and F. W. Bishop, Rochester, N. Y.—p. 851.

Correlation Between Blood Pressure and Nembutal Dosage in Toxemias of Late Pregnancy. J. W. Ross, Washington, D. C.—p. 855.

Clinical Experiences with Ergonovine. J. I. Kushner and P. B. Wahrsinger, New York.—p. 859.

The Management of Pregnancy and Labor Complicated by Triplets. J. C. Hirst, Philadelphia.—p. 868.

Hyperplasia in Epithelium of Uterine Tubes. E. Allen, New Haven, Conn.—p. 873.

Tubal Pregnancy: Analysis of 445 Cases. P. Graffagnino, L. Seyler and M. M. Bannermann, New Orleans.—p. 875.

Pyelitis of Pregnancy Due to Bacillus Dysentery Flexner. H. L. Stewart, Detroit.—p. 887.

Elderly Primiparas.—From Sept. 1, 1932, to March 31, 1937, there occurred in the clinic service 11,919 deliveries with the birth of 12,059 infants. Tew and Kuder found that in this number there were 240 patients who were in the elderly (35 or more years of age) primipara group, an incidence of 2.01 per cent. Among these elderly primiparas there was an increased incidence of toxemia of pregnancy, placenta praevia and myoma uteri. Although there was no marked difference in the total incidence of all types of contracted pelvis, funnel pelvis were definitely more predominant than among the younger primiparas. Among the complications of labor in the elderly primiparas, an increased incidence of occipitoposterior positions, arrested transverse positions and postpartum hemorrhage was observed. The head of the child was unengaged at term in 53.3 per cent of elderly primiparas, as compared with only 20.9 per cent in a control series of patients. The incidence of operative delivery was greatly increased in the elderly primiparas, being double that of the clinic population. Maternal mortality was definitely higher in the elderly primiparas. Infantile mortality, which includes deaths of premature, full-term and neonatal infants, was markedly elevated in the case of elderly primiparas, being almost three times that of the clinic population. The

elderly primipara does not seem to be able to undergo operative procedures at delivery with as good results to herself as does the younger woman, as shown by the complications of the puerperium. Cesarean section is not indicated in the elderly primipara unless there is an accompanying complication, which still further adds to the risk to the offspring.

Acidosis and Alkalosis in Labor.—In an attempt to explain the common occurrence of acidosis Pride and his associates determined the blood carbon dioxide of 157 patients during normal labor. Dehydration and starvation acidosis was eliminated by proper fluids and food. The urine of these patients did not show the presence of acetone and diacetic acid. There was a constant lowering of the blood carbon dioxide as labor progressed, which reached the lowest point at the end of the second stage with recovery to normal immediately following delivery. This is in accord with most observations. The degree of acidosis was always in direct ratio to the hours and character of labor. This increasing acidosis was assumed to be the accumulation of lactic acid resulting from increased muscular activities. Since the presence of diacetic acid and acetone in the urine due to dehydration and starvation and the acidosis evidenced by blood carbon dioxide was found to be in direct ratio to muscular activity the effect of various sedatives was studied. Sodium amytal in eight cases had little effect on the blood carbon dioxide. Three cases showed an average increase of 12.3 per cent of its volume after its administration, while five cases showed a decrease of 11.4 per cent. This indicates that sodium amytal in moderate doses does not produce sufficient analgesia to limit muscular activity. In a few selected cases scopolamine was given in conjunction with sodium amytal. There was a definite rise in the blood carbon dioxide. By increasing pulmonary ventilation scopolamine proved of some value, mainly because it always intensified the sedation, consequently reducing muscular activity. Sodium bicarbonate by mouth was given in a few cases with sodium amytal and scopolamine. The carbon dioxide was elevated from 4 to 24 per cent of its volume, indicating its value as an adjunct with analgesic medication. The correction of physiologic acidosis was attempted by the administration of sodium bicarbonate in 60 Gm. doses by mouth at hourly intervals. There was a definite return of the carbon dioxide to normal in ratio to the amount of sodium bicarbonate ingested. Experimental acidosis was produced in dogs by the administration of intravenous lactic acid and experimental alkalosis by the intravenous administration of sodium bicarbonate. Severe acidosis in the dog was corrected by a 2 per cent solution of sodium bicarbonate without ill effects. Experimental alkalosis in the dog was corrected by a 1 per cent solution of lactic acid. The experimental correction of alkalosis and acidosis in the dog bids to be a valuable adjunct in resuscitating exhausted patients in labor, which conditions have frequently heretofore been fatal.

Extrapulmonary Primary Tuberculosis.—In addition to studying the primary pleural foci, which differ between workers, Sweany and Martinsen analyzed 132 cases of extrapulmonary primary tuberculosis to see whether an infection percentage of the important areas of the body could be estab-

lished for their community. There were 73.5 per cent primary infections involving only the lungs and hilar lymph nodes. There were 79 per cent when the cases with multiple ports of entry were added. There were 8.3 per cent isolated gastrointestinal infections and 12.9 per cent if the cases having multiple ports of entry were considered. There were 1.8 per cent isolated cervical or "head" primaries, which amounted to 4.5 per cent when the cases in which there were multiple ports of entry were added. There were three cases (2.3 per cent) of "pleural" primaries, three cases of "cryptic" lesions in the liver or lymph nodes with no demonstrable local lesion, three doubtful cases and seven (5.3 per cent) in which no calcifications were found. The percentage of cases showing primary hematogenous calcifications in the liver and spleen was 30.6.

Positive Intrapleural Pressure in Pneumothorax.—Since no detailed studies on positive pressure were to be found in the literature, Edsall made an analysis of the pneumothorax treatments administered at Trudeau Sanatorium during the years 1929 to 1933 inclusive. From a total of about 275 patients receiving pneumothorax, sixty-eight were found in whom, at some time during their stay, intrapleural pressures above zero on inspiration had been recorded. All cases were considered in which the pressure had remained positive throughout the respiratory cycle for more than occasional refills. Of the sixty-eight cases, forty-three remained in which positive pressures were induced to a significant degree and sustained over several refills, but in only thirty of the cases were there data adequate for comparing the effects of normal versus positive pressure. In these thirty cases the treatment was applied after a control period on normal pressure. Positive pressure was usually employed to improve a collapse rendered inadequate under normal pressures because of pleural adhesions. In fifteen cases positive pressure produced an increase in collapse of more than 15 per cent; the average increase in the thirty cases was 17 per cent. The increase obtained was not consistently related to the pressure employed. In thirteen cases, healing of cavities under both types of pressure could be compared. Ten cases showed accelerated healing while under positive pressure. In seventeen cases with previously unimproved Gaffky counts, induction of positive pressure was followed within two months by a negative sputum in two cases and a lowered Gaffky count in seven other cases. General results following positive pressure were definitely good in fourteen of the thirty cases and possibly beneficial in seven others. Complications possibly related to the use of positive pressure occurred in four cases. In the thirteen cases in which the effects of pressure were not comparable, two major complications occurred subsequent to the induction of positive pressure. The judicious and careful application of moderate positive pressure is a worth while procedure in selected cases in which simple pneumothorax has failed to produce satisfactory collapse and healing of the lung.

Tuberculosis in Negro Colleges.—In order to determine the extent of tuberculosis case-finding programs in Negro colleges in the South, Cornely and Allen sent questionnaires to 104 collegiate institutions requesting information on the extent and results of tuberculin testing of their students for the school years 1933-1934 through 1936-1937. Thirty-five institutions with an enrolment of 14,162 students, approximately 50 per cent of the total attendance in Negro colleges in the United States, responded. Only one institution has done tuberculin testing on entering students for three consecutive years; two have done it for two years, while three began this practice during the past school year. Based on information from the questionnaires, of 3,542 students in eleven institutions tested during three years, 33.9 per cent gave a positive reaction. The incidence of reactors varied from one institution to another and in the same school from one year to the other. In the summer of 1935 the National Tuberculosis Association made available purified protein derivative tuberculin free of charge to those Negro colleges and universities which were willing to carry out complete tests and to send their results to the association for compilation. Eight Negro colleges took advantage of this offer. Of the 2,040 students tested, the percentage of positive reactors of all ages was 39.1. Reactors gradually increase with age. The percentage of positive reactors was

44 for the male and 35.4 for the female. This is true for practically each year considered. This disparity between the sexes has already been noted in white students, but the inequality seems even greater in the Negro.

Male Hormone and Descent of Testes.—Hamilton has seen cryptorchid testes of the immature macaque descend into the scrotum following adequate administration of testosterone acetate and testosterone propionate. There was less edema and scrotal swelling than in descent produced by gonadotropic substance. Processes considered largely responsible in the production of this descent are (1) growth and elongation of the elements of the cord and (2) slight development of the scrotum to form more of a pouch for the testes. Descent produced by anterior pituitary-like substances may be due in part to stimulation of the secretion of male hormone. Endocrine treatment may be of value in (1) producing descent in certain cryptorchid cases, (2) authorizing surgery at an early age instead of waiting until puberty to see whether spontaneous descent may occur and (3) aiding surgery preoperatively by the development of structures of the cord and postoperatively by preventing retraction and tension.

Carcinoma of Breast in Negro.—Cohn states that during the period from 1932 to 1936 inclusive 481 persons with carcinoma of the breast were admitted to the Charity Hospital. Of these, 256 were Negroes and 225 were white. The per thousand cancer of the breast admissions (Negro) to the total admissions has remained constant, 1.7 per cent for the period under study. More nulliparous Negro than white women have presented themselves with cancer of the breast. The age of the Negro patient averages about 4.7 years younger than the

age of the white patient. The greatest number of cases are in the decade between 40 and 50 years of age in the Negro and between 50 and 60 in the white patient. Metastases in the axillary lymph nodes were present in 60 per cent on admission. Of 224 cases in which the records were adequate for study, only 118 were considered suitable for radical operation. No operation was indicated in twenty-seven cases. These facts further indicate the late period in which the Negro patients present themselves. The percentage of known dead following radical operation is 46. If those cases are added which could not be traced, the percentage dying within from one to five years would be well above 65. Of the 224 patients with carcinoma of the breast considered in this series, probably 75 per cent are dead in from one to four years after their admission to the Charity Hospital. Only 74 per cent of the Negro patients had x-ray investigation preoperatively. Therefore the percentage of skeletal metastases could not be estimated accurately. Irradiation either with roentgen rays or with radium was not the method of choice in any of the operable cases. These data are a challenge to the profession to continue its efforts to educate the public. End results can be improved by methods other than studies of etiology.

Empyema in Children.—Willis observed 104 consecutive cases of empyema in children less than 13 years of age from Oct. 15, 1915, to Oct. 15, 1937. He believes that the punch operation carries a lower mortality if the cavities are kept clean and the general health is improved. It is more difficult to treat these patients by this method than by rib resection and open drainage; but lower mortality, freedom from postural changes, unsightly scar and pus soaked dressings are the compensations. Since the disease rarely occurs as a primary lesion, a careful history must be obtained, especial attention being paid to the possibility of antecedent pneumonia. There was a history suggestive of a bronchopneumonia or lobar pneumonia in 103 cases. Fluoroscopic examinations before and after operation are most important, the former to detect the disease and its extent, the latter to watch the progress of the treatment. Whenever pus is found in the pleural cavity, without the presence of pneumonia, it should be drained through a small rubber tube by the closed method. A rib resection, certainly in the synpneumonic stage, is in the author's opinion dangerous surgery and often the cause of death. The thoracic punch operation is a simple procedure attended with practically no shock. The field is first painted with iodine; a point is selected, usually the eighth or tenth interspace, in the posterior axillary or scapular line, unless there is a localized pocket. The skin is infiltrated for three fourths of an inch, down to the pleura, the needle is changed for a larger one and introduced into the pleural cavity, pus is aspirated, the syringe is disconnected and a half inch incision is made through the skin and deep fascia beside the needle in the line of the intercostal space. The trocar is introduced directly into the pleural cavity so as not to injure the diaphragm. The obturator is pulled out and fairly rigid special tubing about 5 mm. in gross diameter with a lumen of 3 mm. is introduced. It should be twice the length of the cannula and fit snugly and it should reach well beyond the walling-off process of the cavity. The tubing should be rigid enough not to collapse when suction is made with the syringe. If the child is not too ill the pus can be evacuated while the cannula is in position. If there is a large accumulation, the pus should be removed at intervals in order not to reduce the intrathoracic tension too rapidly. Coughing is an indication to stop. The cannula is withdrawn somewhat. An air-tight dressing, consisting of 3 square inches of rubber tissue with a hole in the center, is applied over the tube down to the wall of the chest. The sides of the rubber tissue are then sealed to the wall of the chest with adhesive tape. The tube is doubled on itself and tied off so that the intrathoracic pressure may be reduced gradually by evacuating small amounts of pus at intervals. Irrigations with solution of sodium hypochlorite are employed after operation, when there are many plugs, but not until at least two days or more has elapsed, depending on the general condition of the child. The tube is shortened according to the capacity of the cavity and the fluoroscopic observations. It is removed only when the cavity holds less than 2 cc. and the chest is fluoroscopically negative for any further collections of pus. If the tube is removed

before the cavity is obliterated, though thought to be sterile, there will be a high percentage of recurrence and chronic empyema may result. Postoperative treatment consisting of various chest exercises and general supportive measures should be prescribed and carried out. Rib resection in children should be abandoned except in rare cases and then only after aspiration or thoracotomy has been tried. Rib resections were performed in sixteen of the 104 cases and in eighty-eight the procedure was the trocar-punch operation. In only one child was complete collapse of the lung noted. The average stay in the hospital was 22.5 days. There were five deaths; two occurred in four children less than 1 year of age, two in seventeen children between 1 and 2 years of age and one in a group of thirty-one children from 3 to 5 years of age. There were no deaths in the forty-three children from 6 to 10 and the nine from 11 to 13 years of age.

Lung Abscess.—Rives and his colleagues determined the causes of death in 100 consecutive fatal cases of nontuberculous abscess of the lung, exclusive of any due to tumors, foreign bodies or bronchiectasis. The duration of the disease before treatment, the extent and severity of the infection and the methods of treatment employed were not the primary contributing causes of death. Three more or less controllable factors contribute, in an important degree, to the mortality. They are spreading pneumonitis, empyema and anemia. Anemia may be readily controlled by transfusion and by adequate supportive treatment. Empyema may be avoided in most instances if surgical treatment is instituted early in superficial lesions and if needling of the chest is abandoned. Spreading pneumonitis, the chief cause of death, may be minimized if the following are avoided: attempts to drain the abscessed cavity during the acute stage; compression therapy, especially when the cavity is incompletely drained; all measures such as intermittent postural drainage likely to cause severe paroxysms of coughing while the cavity is full, and surgical drainage in the acute stage and at any time in deep seated abscesses. Approximately half of the deaths were probably not preventable, but in many of the remaining fatal cases the fatality might have been avoided by adequate supportive treatment combined with the judicious use of commonplace methods of bronchial or external surgical drainage. Spreading pneumonitis was the cause of death in four fifths of the fatal cases. The best results will be attained by an orderly plan of treatment which utilizes supportive measures, bronchial drainage and surgical drainage according to their proper indications, and which is continued until the abscess has disappeared completely.

Treatment of Dermatitis by Cataphoresis.—Lowenfish treated twenty cases of chronic occupational dermatitis, ten cases of dermatophytosis and nine cases of moniliasis by cataphoresis with tap water. In the first twenty cases the rapidity of response was striking. In most cases itching was relieved and the appearance much improved after one or two treatments. Clearing up the last traces of the eruption required a longer time, but in all twenty cases the skin became practically normal. Two patients experienced relapse while under observation, but the condition again cleared after two or three treatments. In the ten cases of dermatophytosis and the nine of moniliasis in which the diagnosis was established by microscopic and cultural examination, from two to ninety-one treatments by cataphoresis were given, but the method was of no

value. Ten of the cases of chronic dermatitis of the hands and feet were followed after treatment was stopped and the eruptions disappeared and they have not recurred in six after a follow-up period of from one month to two years. No explanation can be offered as to why this treatment was beneficial.

Blood Cholesterol in Heart Disease.—Poindexter and Bruger determined the cholesterol content of the blood in sixty-one patients with cardiac disease; eighteen had rheumatic heart disease, twenty-four had arteriosclerotic heart disease and nineteen had hypertensive heart disease. Thirty-three normal subjects were used for a comparative study. It was observed that whereas 28 per cent of the patients with rheumatic heart disease had blood cholesterol values below 150 mg. per hundred cubic centimeters, not one of the patients with either arteriosclerotic or hypertensive heart disease exhibited a similar hypocholesteremia. Only 5 per cent of the patients with rheumatic heart disease showed a concentration of cholesterol in the blood over 250 mg. per hundred cubic centimeters, approximately 45 per cent of the patients with either arteriosclerotic or hypertensive heart disease demonstrated this hypercholesteremia. Little or no difference could be observed as to the distribution of the blood cholesterol values when the patients with arteriosclerotic and those with hypertensive heart disease were compared. The cholesterol content of the plasma tended to be low in rheumatic heart disease and elevated in arteriosclerotic or hypertensive heart disease. The results for the group with rheumatic heart disease were not significant since the difference between the means for the group of normal subjects and those for the group with rheumatic heart disease divided by the standard error of the difference of these means gave a value of only 1.03. However, when the same calculations were employed for the patients with arteriosclerotic and those with hypertensive heart disease the results were 4.9 and 4.29, respectively. No appreciable difference was observed in the ratios of ester to free cholesterol in the three types of heart disease considered.

External Secretion of Pancreas.—McCaughan and his associates made physiologic observations on the external secretory function of the human pancreas on a patient in whom a pancreatic fistula developed after a second Billroth type of gastric resection. The fistula was later successfully transplanted to the anterior wall of the stomach. Preceding the operation the effect on the rate of secretion and on the total base was determined before and after the administration of various drugs and foodstuffs. The volume of pancreatic juice secreted in twenty-four hours was estimated at 600 cc. A rise in secretory rate followed the administration of secretin, a mixed meal,

water, hydrochloric acid, beef broth, dextrose, olive oil, peptone, coffee, mecholyl and physostigmine. A fall in the secretory rate occurred after sodium bicarbonate, bile salts, magnesium sulfate, atropine, epinephrine and histamine. The total base was elevated after the administration of secretin, sodium bicarbonate and coffee and was depressed after the administration of a mixed meal, beef broth, dextrose, bile salts, physostigmine, epinephrine and histamine. There was no significant change in total base after the exhibition of hydrochloric acid, peptone and magnesium sulfate.

Changes in Refraction of Atropinized Eyes.—In an attempt to determine the net average yearly changes in static refraction in atropinized eyes from birth to the end of the fifty-first year, Brown made 8,820 observations and computed the changes in the refraction of one or both eyes of 1,203 persons (611 clinic patients and 592 patients from private practice). From birth to the end of the seventh year hyperopia increased (refraction decreased, average 0.18 diopter) in the average case. From 8 to 14 years the refraction moved toward the myopic side at a rapid rate (increased), and this increase (average 0.23 diopter) continued, though at less than half the rate, up to the age of 20. Thereafter the amount of change was negligible. Up to the age of 33 there was a slight yearly increase of refraction (except for the thirtieth year); from 34 to 42 years the change was uniformly a net average decrease of 0.03 diopter, though this was slight; from 43 to 51 years the net average increase of refraction was again 0.03 diopter (increase of myopia, decrease of hyperopia) in each successive year.

Gastric Secretion and Peptic Ulcer.—During his study of the physiology of the gastrointestinal tract, Babkin arrived at a new conception of the regulation of the secretory activity of the gastric glands. It became evident that under certain circumstances, owing to some defect in the secretory mechanism, gastric secretion may deviate from its normal course and conditions may arise which initiate destructive processes in the gastric mucosa. Histamine is present in the gastric juice, whether the secretion is stimulated by subcutaneous adminis-

tration of histamine, by electrical stimulation of the vagi or by sham feeding in dogs with esophagotomy and a gastric fistula. The concentration of the histamine equivalent of the gastric juice increases or diminishes with the increase or diminution of the rate of secretion of the gastric juice. The source of the histamine equivalent of the gastric juice is presumably the gastric mucosa itself. On the basis of these and other considerations the theory is advanced that the secretory fibers of the vagi during activity liberate histamine or histamine-like substances which stimulate the parietal cells. Since histamine has a strong effect on the blood vessels and is able to produce stasis in the capillaries, which may lead to the formation of erosions in the gastric mucosa, it is emphasized that in considering the causes of peptic ulcer the possible role of histamine must not be overlooked. This is not a new theory of the pathogenesis of peptic ulcer but an attempt to evaluate some of the consequences of abnormal functioning of the gastric secretory mechanism.

Kraurosis, Leukoplakia and Pruritus Vulvae.—Since August 1934, Usher and Campbell have performed resection of the sensory nerves of the perineum on eight patients in whom pruritus proved refractory to nonsurgical measures. The technic described by Learmonth, Montgomery and Counsellor was adopted. While it is true that regression changes do occasionally follow resection of the perineal sensory nerve, one must not lose sight of the fact that carcinoma in this region commonly follows leukoplakia, with pruritus the only symptom and excoriation from trauma the only visible lesion. On the other hand, if biopsies taken at the time of the nerve resection do not reveal malignant changes this procedure will relieve symptoms and does not preclude vulvectomy for carcinoma of the vulva if and when it is detected. Complete relief has been obtained in five of the eight patients for periods varying from five months to two and one-half years. In another case there was complete relief for two and one-half years, when vaginitis and leukorrheal discharge resulted in a slight recurrence which rapidly subsided under appropriate treatment. The patch of leukoplakia had also disappeared. In one patient the nerves could not be excised completely. Relief from symptoms was obtained in the remaining case, but the period of postoperative observation is as yet too short to permit the outcome to be determined. The patients have not been followed sufficiently long to determine whether the relief will be permanent. In the majority of cases in which operation was performed, local applications, roentgen therapy and endocrine therapy had been employed previously without success.

Effect on Donors of Repeated Blood Loss.—In the 1936 epidemic of poliomyelitis in Manitoba, convalescent serum for the treatment of the disease was prepared in the government bacteriologic laboratory. Cadham states that it was found expedient to have each of the 125 donors return at intervals and on each occasion to withdraw from 65 to 140 cc. of blood. Fifty of the 125 donors supplied blood six or more times (the maximum was twelve donations) at an average interval of one week. An investigation of the physical condition of the donors six months later disclosed no ill effects. Forty-seven of the fifty donors stated that they were improved in health; even those who were in apparently good health remarked on an increased feeling of well-being. Sixty-five of the donors experienced an improvement in appetite and seven commented on a clearer and healthier tone of the skin. Three donors had been subject to scattered acne pustules; within six weeks of the first withdrawal of blood this eruption disappeared. Seventy-two of the donors increased in weight, the increase varying from 3 to 15 pounds (1.3 to 7 Kg.). There was no decrease in the complement power of the blood, and the titer remained at the same normal level. No variation in blood volume was noted. No donor had anemia. Each of these donors one or more years previously had suffered from an attack of poliomyelitis. Four were far from robust; however, they had been selected because their blood carried a high titer of neutralizing substances. There was a definite improvement in the general health of the latter four donors; they stated that they were able to move about with less difficulty, which would indicate an improved muscle tone coincident with the improved health and increase in weight. Of 200 donors from whom from 50 to 75 cc. of blood was withdrawn on alternate

days over a period of from six to ten days for the purpose of obtaining normal human serum to be used in the treatment of patients with septicemia, none suffered any ill effects; the majority were benefited by the procedure. Why the removal of limited quantities of blood benefit the donor is not clear; obviously, it is not so much a question of disease as of physiology. The increased well-being and the increase in weight are apparently physiologic; the disappearance of acne pustules indicates a stimulation of certain immunity factors. Evidently, under certain circumstances the withdrawal of limited amounts of blood at regular intervals may prove of decided therapeutic value.

Effect of Eclamptic Blood on Urinary Output and Blood Pressure.—Page undertook to determine whether the transfer of 400 cc. of blood from patients with severe pre-eclampsia or eclampsia to normal pregnant women would have any effect on the blood pressure, urinary output and symptomatology of the recipient and, by standardization of the procedure, to discover in eclamptic blood traces of posterior pituitary in excess of the amount that might be present in normal blood. Thirty-seven determinations of antidiuretic effects together with blood pressure curves were performed on twenty-eight patients. As little as 0.01 unit of solution of

posterior pituitary may be readily detected on suitably prepared human test subjects. Transfusions of 500 cc. of blood from normal donors does not result in a significantly altered blood pressure or urinary output in the recipient, although the results suggest the presence of traces of posterior pituitary in normal blood. If small amounts of solution of posterior pituitary are added to human blood in vitro and allowed to stand for from thirty to sixty minutes before transfusion, a definite antidiuretic response may be obtained in the recipient. If large amounts of solution of posterior pituitary are given to donors prior to the withdrawal of blood, no definite antidiuretic response can be obtained in the recipient, indicating a rapid elimination or destruction of the hormone from the circulating blood stream. When amounts of 400 cc. of blood are rapidly transferred from patients with eclampsia or severe preeclampsia to normal pregnant women, the recipients do not show any rise in blood pressure, interference with diuresis or untoward symptoms. The results do not support the contention that there is a toxic substance in toxemic blood or the theory that there is a hypersecretion of the posterior pituitary in eclampsia.

Heat Stroke.—Ferris and his colleagues studied forty-four patients with heat stroke admitted to the hospital during two severe heat waves in 1936. Cardiac failure or peripheral circulatory collapse was not evident in the majority of patients. The sodium chloride content of the blood was not significantly altered. The condition was associated with a moderate acidosis and hemoconcentration. The high body temperature appeared to be the chief cause of the symptoms of heat stroke. Old age, degenerative disease and acute alcoholism are important contributing factors in heat stroke. The onset was precipitated by a diminution or cessation of sweat in the majority of patients. Although the primary cause for the sudden cessation of sweat has not been determined, it appears that loss of chlorides, dehydration and circulatory failure are not responsible. Measures to lower the body temperature promptly are indicated; ice water tubbing with massage was the most effective method in severe cases.

Alcohol and Water and Electrolyte Balance.—Nicholson and Taylor ascertained the effect of alcohol in moderate quantities on the water and salt balance in healthy, young adult male volunteers. They were allowed to carry on their usual routine as students. A constant diet was given. Two duplicate samples of the diet were analyzed for the potassium, sodium, chloride, water and nitrogen content. The day was divided into three periods of eight hours. The urine was collected for each period, toluene added as a preservative and the specimens were kept in the ice box until used. The stools were collected for twenty-four hour periods. The blood samples were collected anaerobically, heparin being used as the anticoagulant. The subject was given alcohol in the form of whisky, gin or ethyl alcohol over a period of eight hours, when a second blood sample was obtained. The third and fourth blood samples were obtained eight and thirty-two hours respectively after consumption of alcohol. Five complete balance studies were made, the results of which were consistent regardless of the form in which alcohol was taken. Data reveal that there was a retention of sodium, chloride and potassium. A small amount of water was lost during twenty-four hours but this loss was more striking during the eight hour period in which the alcohol was given. Diuresis was produced and occurred always in the first four hours of the period, so that during the last four hours only small amounts of urine were voided, even though alcohol was taken during this time. Although there was a diuresis of water, the sodium, chloride and potassium ions were retained and their concentration in the urine was lowered. Accompanying the water diuresis, which occurred only while the subject was taking alcohol, there was a loss of weight greater than could be accounted for by the loss of water in the urine alone. The retention of the sodium and the chloride was greater when the intake of these ions was high, and in the two experiments in which the sodium chloride intake was inadequate there was a negative balance for these ions. In all experiments the potassium retention was great and apparently had no relationship to the amount of sodium or chloride retained. Potassium in excessive amounts

is a depressant and produces malaise, nausea, vomiting and headache, all of which symptoms are observed after excessive ingestion of alcohol. The increase in the concentration of plasma potassium after the ingestion of alcohol may be responsible for some of the after-effects of overindulgence in alcohol. The unpleasant symptoms of postalcoholic excess appeared at a time when the concentration of alcohol in the blood had fallen and when the potassium concentration was at its maximum.

Excretion of Urea in Glomerulonephritis.—Chasis and Smith determined the urea clearances in ten normal subjects and twenty-two subjects with glomerulonephritis, with special reference to the degree of concentration of the glomerular filtrate as indicated by the simultaneous inulin U/P ratio (the degree to which the glomerular filtrate has been concentrated by the reabsorption of water). Urea is invariably reabsorbed to some extent from the glomerular filtrate, whether this is at the normal level or is reduced by disease. This reabsorption is interpreted in terms of a hypothesis, based on independent evidence, in which it is assumed that water reabsorption occurs in two stages, one in the proximal tubule and one in the thin limb and distal tubule. At any inulin U/P ratio the reabsorption of urea proceeds in the nephritic kidney essentially as it would in the normal kidney. As the capacity to reabsorb water is impaired by disease, the fraction of urea reabsorbed decreases, so that the urea clearance approaches the rate of glomerular filtration. In none of the subjects examined was there evidence of increased back-diffusion of urea, the elevation of the blood urea in nephritis being a result solely of the reciprocal relationship between this term and the urea clearance, as expected in principle.

Leukocytic Variability and Meteorologic Alterations.—The influence of the meteorologic alterations on the daily leukocyte count of four normal individuals was studied by Berg. The average level of the count and the degree of fluctuation varied with each individual. Variations in levels with constitutional differences were also observed. The neutrophilic

levels are slightly lower in winter in subject 1 and almost the same level in subject 3; however, both basophilic and eosinophilic levels are noticeably elevated in both in the winter. In general, the more pronounced the polar infalls the more pronounced are the peaks in the leukocyte picture. The meteorologic alterations have been shown for the most part to be associated with pressor episodes. Following these, there then occurs a vascular dilatation with a fall in diastolic pressure which is associated with an increase in the eosinophils, the appearance of more young forms, and an increase in the neutrophils and in the total leukocyte count. The fluctuations may in part be explained by the emptying of the reservoirs of cells, such as the spleen, liver and lungs. The daily records of five patients (one each of aleukemic lymphadenosis, myelogenous leukemia, lymphatic leukemia, chronic far-advanced pulmonary tuberculosis and far-advanced pulmonary tuberculosis) are presented. The degree and character of the fluctuations were influenced to varying degrees by the pathologic condition of the patient.

Abnormal Blood Pigment After Sulfanilamide.—Posner and his associates encountered four cases showing a specific effect of sulfanilamide therapy. In these patients, spectroscopic examination of the blood showed that the abnormal appearance of the specimens was associated with an absorption band in the red part of the spectrum. When the blood was diluted just enough to allow for the passage of light, this band divided the red-orange field into two parts occurring roughly in the ratio of 55:45, the line being slightly nearer the yellow end. On spectrometric measurement the density center of the absorption band, which was not sharply defined, was located at 634 millimicrons (the position given for methemoglobin by Bodansky). That the pigment encountered was not sulfhemoglobin was demonstrated in several ways. The methemoglobin was highly unstable, thus interfering with detection and quantitative determination. Cyanosis associated with methemoglobinemia is temporary and responds promptly when the causative agent is withdrawn. Except in mild cases, cyanosis occasioned by sulfhemoglobin persists for weeks, since the pigment is extraordinarily stable. Although the cyanosis associated with sulfanilamide therapy may cause no clinical concern so long as it is due to methemoglobin, the possibility of the development of sulfhemoglobinemia should not be ignored. Sulfhemoglobin (never methemoglobin) may be detected by spectroscopic examination of a transilluminated ear lobe. Since it is the absolute level of nonoxygenated hemoglobin which determines the presence or absence of cyanosis, sulfanilamide administration must be undertaken cautiously when the total hemoglobin concentration is low. If the erythrocyte count is normal and remains so (twice weekly checking is advisable), the appearance of definite cyanosis is a signal for temporary cessation of the therapy. With anemic patients, however, this warning is lacking. Spectroscopic examination may not suffice to indicate danger.

Folin-Malmros Micro Blood Sugar Method.—In determining blood sugars by the Folin-Malmros micromethod, Jourdonais obtained capillary and oxalated venous blood in the usual way. The technic of the method used is essentially that recommended by Folin and Malmros, with the exception of the length of time for heating. The tubes were placed in the water bath for twenty minutes. A 0.001 per cent dextrose solution was used as a standard. The directions for use of the colorimeter given by Goudsmit and Summerson were followed. A yellow glass filter proved to be of advantage. A high intensity of light increased the sensitivity of the colorimeter. It further resulted in a saving of time by making it possible to approach the null point of the galvanometer more rapidly. A yellow filter is advantageous for securing consistent results. The readings with the colorimeter do not follow Beer's law, and a calibration curve is necessary for accurate results.

Congenital Syphilis.—Though only thirty-seven new cases of congenital syphilis have been observed in two years in the University and Ancker hospitals, it is evident that many of these could have been prevented. Lynch attempts to determine the reason for failure of preventive measures and in many of these cases it has been possible to place the responsibility for the failure. Future attempts toward the control of congenital syphilis require greater interest on the part of the medical profession and the provision of more adequate social service and health department facilities. The following procedures are suggested as methods for the prevention of congenital syphilis and its serious effects on the child: 1. Every woman with gonorrhea should have a Wassermann test in order to recognize early many cases of syphilis which are now passing unrecognized. 2. Every syphilitic woman should receive adequate treatment but should also be warned of the need to report to her physician early in any subsequent pregnancy and inform him of her syphilitic status. 3. Every pregnant woman should have a Wassermann test done early in pregnancy. 4. After the diagnosis of syphilis is made during pregnancy, treatment should be intensive. 5. At the time of delivery a Wassermann test should be performed on the maternal blood or the "cord" blood in every case.

Sulfanilamide in Gonococcic Urethritis.—Spink and Gaston present the results of treatment and immunologic observations in twenty-one men with acute gonococcic urethritis treated with sulfanilamide. The patients were ambulatory. Eight of them had received previous treatment without diminution of their symptoms. With a few exceptions the only treatment prescribed was sulfanilamide and the forcing of fluids. Most of the patients continued at their daily occupations while under treatment. All were first given 4 Gm. of sulfanilamide daily in four divided doses. Sometimes the dose was reduced to 2 Gm. a day so as to determine the effect on the course of the disease and on the bacteriolytic titer of the blood. The drug was administered for from ten days to three weeks. It was continued as long as evidence of the infection was still present. Eleven patients were declared cured, seven had no urethral discharge but could not be proved as free from infec-

tion and three failed to respond to treatment. The administration of sulfanilamide results in an increase of the bactericidal power of the blood against the gonococcus. A high bacteriolytic titer is desirable in patients with gonococcal infection, since the action of bacteriolysins has been shown to be a major mechanism in rendering the blood stream free from organisms. While a high bacteriolytic titer is an expression of humoral immunity, it cannot be correlated closely with local immunity. Spink and Keefer have shown that, while the blood stream may be rendered free from gonococci by the introduction of immune horse serum, organisms may still be present in prostatic secretions. This was illustrated in the present study by the three patients classified as failures. The bactericidal power of the blood was elevated while sulfanilamide was being administered, but the urethral exudates persistently contained gonococci. It may be argued from these cases that, although the bactericidal tests done against two strains of gonococci showed the drug to be effective, the actual strain harbored by the patient would not be affected by sulfanilamide. Since the bactericidal mechanism is important in clearing the blood stream of organisms, sulfanilamide should be a useful adjunct in the treatment of local gonococcal infections.

Prevention of Foot Drop in Prolonged Bed Rest. D. R. Loree, Ellensburg, Wash.—p. 147.

Large Twins.—A more or less thorough survey of the literature revealed only three reports regarding large twins with a combined weight of 7,000 Gm. or more. Through personal communications Mathieu collected seventeen additional reports of large twins. The highest combined weight of the twins in the series, excluding enormous twins reported by Warren (combined weight of 16,102 Gm.) is 9,180 Gm., the lowest 7,000 Gm. The smallest individual child weighed 3,400 Gm., the largest 4,670 Gm. The sex of the twins in this collection was mentioned in only six instances. In five, both babies were males. In the sixth (the author's), one was a male and the other a female. The male infant was 170 Gm. heavier, the combined weight was 7,880 Gm.

Bacteriology of Spreading Peritonitis.—Bower and his co-workers studied the bacteriology of spreading peritonitis in living man and in dogs during life and at necropsy in an effort to establish the identity of the causative organisms. Specimens for cultures were removed from fifty-five patients suffering from gangrenous appendicitis associated with spreading peritonitis. Cultures were taken from the peritoneal cavity of 154 dogs. The number and kinds of aerobes in spreading peritonitis in man are greater than those found in the dog. The greatest increase is in *Bacillus coli*, 396 per cent. Four of the five members of the streptococcus group were found in the dog. This group was 81.7 per cent greater in the human being than in the dog. On the other hand, *Staphylococcus albus* was found in the dog and not in man. There is a close resemblance of the anaerobic flora in the two groups. In man *Clostridium welchii* was found in 63 per cent. The only appreciable difference in percentage between the two groups, as concerns *Clostridium welchii*, was in the association of this organism with other anaerobes and aerobes; in man this was 40 per cent as compared with 29 per cent in the dog. A gram-positive anaerobe, not identified but not *Clostridium welchii*, was found in 17 per cent in man and 6 per cent in the living dog. Anaerobic streptococci and *Vibrio septique* were the only two important anaerobes identified in the cultures taken from the dog that were not found in man. Obligate anaerobes and *Bacillus sporogenes* were found in human cultures but not in the dog. The *Bacillus histolyticus* was not found in either group. Gram-positive diplococci and cocci were not found in man.

Primary Carcinoma of Biliary System.—D'Aunoy and his associates base their study on the clinical records, the necropsy observations and the gross and microscopic appearances of preserved specimens in forty cases of primary carcinoma of the biliary system encountered among 6,050 necropsies. The study is particularly concerned with the site of the primary growth, its structure, its spread locally and to distant parts, its clinical manifestations and their duration and the immediate cause of death in the patient. Of the forty tumors, twenty-three were primary in the liver, six in the extrahepatic biliary ducts and eleven in the gallbladder. Twenty of the patients were Negroes (eighteen male, two female) and twenty were white (twelve male and eight female). Of the twenty-three primary neoplasms of the liver, sixteen were liver cell and seven were cylindric cell carcinomas. All those primary in the extrahepatic biliary ducts and gallbladder were cylindric cell carcinomas. In the six cases of carcinoma of the extrahepatic biliary ducts, the primary growths were small, not more than 1 cm. in diameter. In four of these the common bile ducts and in two the common hepatic ducts were the site of the growth. In all six cases, however,

the neoplasms obstructed the duct lumens, causing dilatation of their proximal portions with resultant jaundice. All but one of these patients had calculi in the gallbladder. In the eleven cases of primary carcinoma of the gallbladder, the walls of the organ were thickened by neoplastic infiltration. A fungating mass protruded into the cavity of the organ in four of the cases, and biliary calculi (mixed gallstones) were present in seven. The microscopic structure of the liver cell carcinomas varied. Variations in the structural arrangement of the cells, the amount and quality of the stroma and the extent of secondary changes, such as hemorrhage and necrosis, were responsible for the differences in microscopic and gross appearances of the growths. In many instances, in addition to local infiltration or spread by lymph and blood channels, the growths metastasized to regional lymph nodes and distant organs. The majority of the patients with liver cell carcinomas were jaundiced and showed cirrhosis of the liver with ascites. All six patients with primary cylindric cell carcinomas of the extrahepatic biliary ducts were jaundiced, six had cholelithiasis (mixed gallstones) and one had cirrhosis of the liver with ascites. Four of the eleven patients with primary cylindric cell carcinomas of the gallbladder had cholelithiasis, jaundice and cirrhosis of the liver with ascites; one had cholelithiasis, jaundice and cirrhosis; one had cholelithiasis and ascites; one had cholelithiasis and cirrhosis; one had jaundice and cirrhosis, and one had cirrhosis only. The temperature of all the patients, irrespective of the type or location of the tumor, showed only slight variations from the normal. The illnesses lasted for from two to sixteen months, with an average duration of four and one-half months. In all but two of the patients in whom the neoplasms were incidental observations the new growth was the principal lesion, and in twenty-five patients it was the immediate cause of death.

Bacteria in Sutures.—Clock examined thirty-six brands of surgical catgut sutures and found fifteen brands to be nonsterile. Of the 589 lots tested 161 lots contained nonsterile sutures. From the nonsterile catgut sutures, thirty-six spore-forming bacterial species were isolated and identified; including five sporulating anaerobes together with thirty-one aerobic and facultative spore-forming bacilli. All the aerobic and facultative spore-forming bacilli, together with two species (*Clostridium bifermentans* and *Clostridium sporogenes*) of the sporulating anaerobes, are commonly considered nonpathogenic; but the three other species of sporulating anaerobes (*Clostridium fallax*, *Clostridium histolyticum* and *Clostridium welchii*) are pathogenic. Some sutures of some brands of catgut contained aerobic and facultative spore-forming bacilli which are nonpathogenic, while in other sutures of the same lot were found pathogenic, sporulating anaerobes. On chemical analyses of sutures of those brands of catgut which proved to be nonsterile, appreciable quantities of soluble chemical compounds were found. The physical characteristics of these sutures indicated that they had been subjected either to a low degree of heat or to no heat.

Scopolamine in Obstetric Practice.—In the use of scopolamine as an obstetric analgesic Bell found that there were some inexplicable deaths. In an endeavor to determine whether or not these deaths were directly attributable to the use of scopolamine, he made an analysis of 441 consecutive cases personally treated over a period of three years. Scopolamine had been used in 225 cases, and pentobarbital sodium was substituted for scopolamine in 216 cases. Scopolamine was usually effective in producing a desirable degree of amnesia and analgesia, but its cumulative effect on the respiratory center of the infant so often resulted in fetal asphyxia that the author has not felt justified in continuing its use. Although the dangers to the life of the mother as a result of the use of scopolamine may usually be eliminated, he so fully recognizes the right of the infant to live that he is convinced that neither the mother nor practitioners can justify its use merely in an endeavor to minimize the suffering of the mother in childbirth. His experiences with 216 patients to whom pentobarbital sodium was given instead of scopolamine, without the untoward results sometimes incident to scopolamine, have convinced him that the barbiturates are not only as effective as scopolamine but are far safer for both mother and child.

Staphylococci of the Human Vagina.—Weinstein examined 419 vaginal secretions for the presence of viable staphylococci. Of 196 pregnant patients and 223 with or without disease of the female genitalia, 191 were found to be harboring staphylococci. Eighty-two of the pregnant and 109 of the nonpregnant women yielded staphylococci. Most of the strains isolated were of the albus type, aureus being found in a much smaller number of cases; 90 per cent as contrasted with 9.9 per cent. No correlation could be established between the incidence of the albus type and any particular clinical syndrome. *Staphylococcus aureus* was recovered, however, with the greatest frequency from pregnant individuals. Of the nineteen strains isolated, nine were found in cases of pregnancy, three were recovered from cases of *Trichomonas vaginalis* vaginitis, one from an individual with a retroverted uterus, four from cases of "nonspecific" vaginitis, one from an individual with dysmenorrhea and one from a patient in whom there was no pathologic change of the genitalia. The albus type of staphylococcus deserves further study in its possible relation to disease of the female genitalia, since many of the types isolated possess the property of hemolyzing blood, occasionally coagulate serum and ferment mannitol which, according to Chapman, are indicative of potential pathogenicity.

Effect of Sulfonamide Compounds on Bacteria in Vitro.—Britton observed the effects of five sulfonamide compounds on fifty strains of twenty different organisms (bacillus, staphylococcus, streptococcus, brucella, clostridium and micrococcus) by a simple in vitro method. Of these twenty, only in the cases of *Streptococcus viridans* and *pneumococcus* types 1 and 2 and group 4 were any bactericidal or bacteriostatic effects observed.

Protective Serums Against Hemolytic Streptococci.—Loewenthal finds that the antigen responsible for the production of the antibody effective against the invasiveness of hemolytic streptococci is intimately associated with the capsule which these cocci develop in the early hours of growth in culture. This antigen is extremely labile, being readily destroyed by heat and low concentrations of formaldehyde or merthiolate. Exposure of a suspension of young encapsulated cocci to a temperature of 55 C. for twelve minutes kills the organisms but leaves the capsular antigen intact. More prolonged heating at this temperature rapidly destroys this antigen. With suspensions of cautiously heat-killed young cultures it has been possible for the first time to prepare potent protective serums against hemolytic streptococci in the mucoid phase. This method of immunization also gives rise to protective antibody against nonmucoid strains more rapidly and regularly than the old methods. The result of a single experiment suggests that the production of a potent polyvalent serum by simultaneous immunization with a number of strains is possible.

Increased Prevalence of Dysentery in Glasgow.—During the past three years the annual number of cases of dysentery registered in Glasgow has been increasing and has become relatively high. During the second half of 1937 the city with 203 cases shared in the reported countrywide increase in prevalence. Bloch reviews some aspects of the prevalence of dysentery during these years and of raised incidence on previous occasions. Dysentery became notifiable in 1919, when 117 cases were registered. The annual average over the whole period 1919 to 1937 was 81.4 cases. Reports from various sources regarding the seasonal incidence of dysentery differ widely.

The years under special review here might be regarded as revealing some resemblance between the seasonal incidence of dysentery and that of the other diarrheal diseases. Deaths from diarrhea and enteritis are highest in either the third or the fourth quarter of the year. Despite the increased attention paid recently to dysentery, many mild and many bacteriologically negative cases remain unnoticed. Suspicion of dysentery may not be raised when cases do not occur in groups. Institutional infections form a substantial and increasing proportion of the total number of cases. The excess of total cases for 1937 over 1936 is accounted for by institutional cases. Some relation does probably exist between the institutional and the home cases. The gross figures for all cases of dysentery without subdivision according to type of bacillus revealed no special feature with regard to sex incidence. The figures with respect to the age of incidence of both institutional and noninstitutional cases confirmed the recognized high incidence of dysentery in children between 1 and 15 years of age. Deaths certified as due to dysentery remain few. Sixteen persons died of dysentery in 1936 and nine in 1937. A majority of the cases of bacillary dysentery are probably still due to the Flexner type of organism. During the years 1929 to 1936 positive specimens from Glasgow, according to the city bacteriologist, have numbered 413 Flexner and 278 Sonne. It is not uncommon to find different types and strains of endemic dysentery organisms associated in a multiple focus. The first large Glasgow outbreak of Sonne dysentery occurred in a big general municipal institution toward the end of November 1937 and continued till the end of January 1938. In December forty-two cases were registered from this focus and only two from other Glasgow institutions. Home infections numbering twenty-eight were also registered in Glasgow in December. The seventy-two December cases thus constituted more than a fourth of the year's 272 cases. The epidemic assumed the form of two successive waves of infection. There was no definite evidence of spread of infection by food, milk or water, but it was thought important that the milk supplies should be scalded in the wards and attention devoted to the methods of cleansing food utensils, especially milk containers, passing through the central kitchen and dairy premises. No incidence of Sonne dysentery was detected in these departments, all the members of the staff of which were examined bacteriologically.

Carcinoma of the Palate.—Nuttall presents an analysis of 167 cases of malignant palatal ulceration and of 104 cases of antral carcinoma passing through a single clinic. As a result of the investigation it is suggested that the tendency to recurrence after treatment of carcinoma of the palate is due to the fact that a large proportion of "palate growths" are really neoplasms of the antrum. With certain limitations it is a wise generalization that every case of carcinoma of the palate must be considered and treated as an antral growth unless it has been proved not to be so.

The Heart in Gallbladder Disease.—Laird determined the condition of the heart in sixty-five consecutive cases of disease of the gallbladder and the biliary tract. There were fifty-eight women and seven men. Fifty of the patients had a clinical cardiac lesion. Of the sixty-five patients, twenty-four were regarded as obese. This suggests that the obesity, if a factor, is not the whole explanation of the presence of cardiac lesions in these cases of disease of the gallbladder. Fifty patients were followed up or were under observation until death occurred. Operation was performed in forty and thirteen of these had cardiac manifestations. Cholecystectomy produced a cure of the symptoms of gallbladder disease in 78 per cent of cases in which this operation was performed and appeared to be a satisfactory measure for obtaining amelioration of the cardiac manifestations occurring in cases of disease of the

gallbladder. The presence of similar cardiac conditions in cases of disease of the gallbladder does not constitute a contraindication to cholecystectomy. Fatal pulmonary embolism occurred as a postoperative complication in 5 per cent of the cases. There was some evidence to suggest that the longer disease of the gallbladder is permitted to exist the greater is the possibility of cardiac manifestations making their appearance. The incidence of lesions of the heart in cases of disease of the gallbladder was not influenced by the presence of jaundice. Coronary artery thrombosis occurred in 12 per cent of the cases and on occasion may present difficulty in differential diagnosis. The electrocardiographic evidence was inconsistent in many cases of myocardial insufficiency when compared with the clinical condition of the patient but was of great value in cases in which coronary artery thrombosis had occurred.

Physical Signs in Lobar Pneumonia.—Lobar pneumonia may present, in place of the classic physical signs, abnormal signs confusing the diagnosis even when the onset, symptoms and temperature all seem conclusive. These perplexing features require explanation and this Erwin and McGill believe can be found only in the physiologic and pathologic changes in the underlying lung, since physical signs in themselves, even when taken in groups, are not conclusive proof of any particular disease. Thus the consolidation of pneumonia due to alveolar exudate is usually evidenced by dullness to percussion and by bronchial breathing, and these are the accepted signs of the disease. When alveolar exudation is complicated by bronchial filling there is produced a different group of physical signs—those of a solid lobe with a blocked bronchus. A complete absence of breath sounds is discovered, together with other signs suggestive of a moderate accumulation of fluid.

Rheumatic Infection in India.—In order to determine the incidence of rheumatic infection Mangalik and Stott reviewed the Thomason Hospital records for the years 1930-1936. During this period there were nine cases of acute rheumatic infection, giving an admission rate of 1.17 per thousand medical admissions. For every case of acute rheumatic infection admitted to the hospital during the period under review, fourteen cases of chronic valvular disease, mostly of mitral and of undoubted rheumatic origin, were admitted. One is justified in drawing the conclusion that the initial rheumatic infection in Indians is rarely fulminating and acute and rarely compels the patient to seek hospitalization; it probably has a slow, insidious course and onset—mostly vague pains in the body and joints and not severe enough to confine the patient to bed. The most common age for acute rheumatic infection is between 5 and 15 years. The most common age for the patient to seek hospital aid for cardiac disabilities connected with a chronic mitral valvular lesion is between the ages of 20 and 35. There is no definite distribution in the sex or caste of the patients, nor is the monthly admission rate of any great significance. Rheumatic nodules are rare. Acute rheumatic infection in India, with polysynovitis, carditis and chorea, though rare in the hospital-going class of Indians, is a definite clinical entity to be seen in India.

Fetal Mortality in the Offspring of Healthy Women.

—On the supposition that frequent abortions and stillbirths may be due to some endocrine abnormality, i. e., a deficiency or excess of essential hormones, Potter performed a series of Aschheim-Zondek tests on the urine of nineteen pregnant women who had previously been unable to carry a pregnancy to term, to see whether the reactions differed from the reactions obtained from the urine of normal pregnant patients. Although the urine of pregnant women who produced stillbirths and abortions frequently gave perfectly normal Aschheim-Zondek reactions, the results were definitely weaker than those with the urines of normal pregnant patients. The nineteen patients with a history of habitual stillbirth and abortion were placed on large oral doses (up to 18 grains, or 1.2 Gm., daily) of corpus luteum (progesterin). Three of these cases ended in failure. There were six cases of threatened abortion in this series, in each of which the pregnancy was preserved. This series of cases of habitual stillbirths and abortions gives a high percentage of pregnancies successfully terminated, especially compared with what the same patients accomplished unaided by progesterin. Without this treatment the nineteen patients had among them fifty-five pregnancies. Of these only eight were successful and forty-seven ended in failure. The same nineteen patients, under treatment with progesterin, achieved success with sixteen pregnancies and only three failed. It is suggested that the factor in the corpus luteum responsible for these successes is probably different from the factor responsible for the structural changes of the endometrium preparatory to pregnancy. It is further suggested that theca lutein cells produce the hormone which inhibits uterine contractions and which probably remains potent if given orally.

Diagnosis of Intra-Uterine Death.—Jones outlines a spectrographic method of diagnosing intra-uterine death of the fetus. It is based on a specific spectroscopic change that can be demonstrated in the urine of women carrying a dead fetus. Pure estrogen was found to exhibit selective absorption, with a broad band having its maximal absorption in the ultraviolet near 281 millimicrons and a minimal about 260 millimicrons. Both theelin and theolol have almost identical absorption curves. Accordingly, the absorption intensity of all the estrogenic extracts was measured at 281 millimicrons. Extracts from urine of normal and abnormal pregnancy were obtained and after all the theelin and theolol were extracted (by means of the two technics) all were found to display a characteristic absorption band in the same region as that of pure estrogen. Procedure 1: A 200 to 300 cc. sample of urine of pregnancy, adjusted to pH 1 to 2 with concentrated hydrochloric acid, is refluxed at 100 C. for three hours on a water bath. On completion of the hydrolysis of estrogenic complexes, the cold solution is extracted three times with 100 cc. of freshly redistilled ether. The ethereal extract is washed with sodium bicarbonate and water, the solvent is removed and replaced by 5 cc. of specially purified ethyl alcohol and its ultraviolet absorption determined, a 1 to 5 mm. cell being used. Procedure 2: The crude ethereal extract obtained as in procedure 1 is freed from ether, dissolved in toluene and reextracted with normal sodium hydroxide. After the extract is acidified with hydrochloric

acid it is again extracted with ether and examined as in the final stages of procedure 1. It is possible to diagnose intra-uterine death of the fetus by submitting the urinary extracts obtained by both preparative technics to spectrographic analysis. If the fetus is alive there will be an appreciable difference between the two estimations, whereas if the fetus is dead the two estimations will be approximately the same. Twelve patients examined spectrographically showed an absorption intensity from 6 to 18 (by both preparative procedures) considered to be characteristic of intra-uterine death of the fetus, and in each case the patient was subsequently delivered of a macerated fetus. In four other patients in whom intra-uterine death of the fetus was suspected the spectrographic examination of the urine suggested that the fetus was alive and the accuracy of this result was subsequently confirmed, as each pregnancy proceeded normally. In three cases of suspected intra-uterine death the results were misleading. Two of these patients were suffering from toxemia, while the third carried an anencephalic fetus. The hormone balance must be influenced by fetal abnormalities and, therefore, special caution must be exercised when one is applying this test to such patients. The author explains the spectrographic phenomenon by inferring that a substance absorbing in the same region as estrogen is absent, or greatly reduced in quantity, in the urine of women carrying a dead fetus. He is thus led to postulate the existence of a heretofore unrecognized hormone in the urine of a normal pregnancy, with apparently a definite role in normal gestation. Such a hypothesis implies that intra-uterine death of the fetus may be connected sometimes at least with a specific hormone deficiency or imbalance. This hormone imbalance may be either a cause of or a sequel to intra-uterine death. An attempt was made to isolate this unknown product, and ultimately it was traced to the toluene residues of the Marrian technic. From 20 liters of urine, treated in small batches, a few milligrams of the final product was obtained in a crystalline form. This x product showed selective absorption near 294 millimicrons and had a melting point in the region of 225 to 230 C., while its biologic reaction was estrogenic.

Cycle of the Woman.—Samuels points out that a sexually mature woman ovulates twice in each cycle, young nulliparas three times. The ripening of the second ovum suppresses the formation of the corpus luteum of the first ovum by means of hormone. Nidation takes place within three days after fertilization, as all early pregnancy cyclograms indicate. The surface cells of the endometrium die to the accompaniment of bleeding when there is a sudden change or withdrawal of hormone. These cells usually die as a result of the withdrawal of luteal hormone, but it is certain that a sudden cessation of the supply of folliculin can also cause this. Bleeding may also occur in the case of young girls during an ovulation as the result of a sudden and sharp decline in the curve. It may also occur when large quantities of folliculin are supplied to the endometrium and then suddenly withdrawn. A corpus luteum and luteal hormone are not essential to desquamation with bleeding. When the hormone changes are slow the endometrium can recover without bleeding. The mucous membrane is transformed by the second corpus luteum menstruale. Cyclograms tend to prove that in all probability predominating luteinizing hormone of the hypophysis may also incite the first suppressed corpus luteum to form luteal hormone after the second unfertilized ovum has died. The possibility of fertilization is greatest during the ovulation decline and the two to three days preceding it. On the third day after the beginning of the ovulation decline the possibility of fertilization is only slight; thereafter fertilization is impossible. A woman is absolutely sterile for three days after the second ovulation decline until from two to three days after menstruation begins. After this she is relatively sterile until three days before the first ovulation decline. The cyclogram accordingly serves as a guide in determining all processes of ovulation and conception and in diagnosing and treating irregularities of menstruation. The cycloscope (described in THE JOURNAL Feb. 26, 1938, page 696) will therefore prove to be an indispensable instrument not only for the gynecologist but also for all general practitioners.

The Gordon Test in Lymphadenoma.—The discovery that an encephalitogenic agent was present in the lymph nodes from cases of lymphadenoma was first made by Gordon in 1932. In an effort to discover which type of cell contained the agent, Edward has carried out experiments using human cells and also the tissues from certain animals not tested previously. At the same time microscopic examinations have been made of the brains of the experimental animals and the histologic changes induced have proved a reliable test for the agent. It was found that the agent could be demonstrated in the mixtures of mature granular cells and myelocytes obtained from cases of myelocytic leukemia, but not in suspensions composed chiefly of myeloblasts. The one case of eosinophilia examined gave a strongly positive result. Weak positive results have also been obtained with lymphocytes; this is surprising, since suspensions of lymph nodes in lymphatic leukemia always give a negative biologic test (Gordon 1933). The presence of the agent has also been confirmed in pure suspensions of neutrophil leukocytes. No histologic differences have been found depending on the various sources of the agent. The condition of the affected animals during life is the same. The agent in lymphadenomatous glands has the same effect as that in leukocytes. In such diseases as myelocytic leukemia and myelosclerosis, in which there is infiltration of the lymph nodes with myeloid cells, these nodes give a positive test. In lymphadenoma granular cells are usually found in the lymph nodes, the eosinophils being the most conspicuous. If the biologic test in lymphadenoma depends on the cell content of the lymph nodes, its limitations are obvious when used as a diagnostic measure in a case of lymphadenopathy.

Biologic Polyvalence of Antigens.—Freeman and Hughes find that foreign grasses not grown to any extent in England give positive cutaneous reactions in people with hay fever who have not been exposed to them previously. Pollens of maize and bamboo could not be distinguished antigenically from the pollens of English grass. The pollen of sugar cane behaves in the same way as the pollen of English grass in the majority of cases. There is a slight antigenic difference between the pollen of sugar cane and the others, as a minority of the patients desensitized to timothy lost their reaction to sugar cane more slowly. Also three patients were found who were not sensitive to cane pollen but who were definitely sensitive to timothy. A comparison between the pollen of the gramineae and the pollen of garden flowers showed that such exotic "grasses" as maize, bamboo and sugar cane are far more closely related to the pollen of English grasses antigenically than to that of English garden flowers.

Renal Decapsulation.—Godard reviews three cases in which bilateral decapsulation was performed. The first patient was a girl, aged 10 years, who became anuric following an appendectomy and in whom complete remission took place subsequent to decapsulation. At a second intervention, following recurrence three years later, lesions suggestive of chronic glomerular nephritis were observed. Remission occurred after the second operation also. The second patient was a girl, aged 5 years, who presented subacute glomerulonephritis marked by anuria. Death occurred shortly after decapsulation. The third patient was a girl, aged 3 years, who developed nephrosis marked by complete anuria, stomatitis, myosis and prostration, following accidental swallowing of mercuric oxycyanide. Death ensued forty-eight hours after decapsulation. These cases led the author to experiment on the effects of decapsulation on mercurial nephritis and on diuresis: Mercury was administered intravenously to five rabbits, which were then decapsulated. Three of them died, one two hours and two six days after operation. Of the survivors, one was killed ten days later and the kidneys were removed for microscopic study. Of five other rabbits that received mercury but were not decapsulated, three died within ten days and two recovered spontaneously. Accordingly, decapsulation did not benefit the poisoned animals. In another experiment with two rabbits, the volume of urine was measured before and after their decapsulation. The volume decreased temporarily immediately after operation; no appreciable polyuria or modifications of the urea concentration were observed. Since in the first patient a thick fibrous new growth was observed at the second intervention to have replaced the original capsule, the author decided to investigate possible similar formations in experimental animals. Late postoperative examination of decapsulated rabbits revealed neocapsular tissue thicker than the original in two animals, and fibrous layers of variable thickness in two others. Although a comprehensive study of the literature leaves the impression that decapsulation exerts a favorable influence on anuria, definitive therapeutic evaluation of the procedure should be approached with caution. There is the possibility that decapsulation in addition to its direct influence on the kidneys may elicit vascular and nervous reactions, owing to the release of proteolytic products in the operative field.

Comparative Studies on Mycosis Fungoides and Hodgkin's Disease. S. Lapière.—p. 159.

Surgical Treatment in Splenomegalies.—Grégoire emphasizes that the results of splenectomy depend not so much on the surgical technic and on the skill of the surgeon, but rather on his ability properly to evaluate the indications and contraindications to the surgical treatment. Of the splenomegalies, he says that there are those which do not require operative treatment and those which do. The splenomegalies which do not require operation include the splenic hypertrophies of a tumoral nature, such as Gaucher's disease, Hodgkin's disease and leukemia. Aside from the splenectomies in which surgical treatment is dangerous or at least useless, there is another category in which surgery is not necessary. With this group, the author classes all those cases in which medical treatment suffices to affect cure or improvement; for instance, the splenic changes of syphilis, leishmaniasis, bilharziasis and malaria. On the other hand, in the presence of one of these splenomegalies of known cause, in which the medical treatment is of little

influence, recourse to splenectomy may be necessary because of disorders in the blood, the vessels or the liver. Increase in size of the spleen, progressive anemia and hemorrhages are the chief indications for surgery. Before an operation is decided on it is important to determine the functional capacity of the liver. An irregular and hard liver with sharp outlines in a person with poor general condition must be regarded as a contraindication to the operation. The author refuses to perform an operation in cases in which the urea content of the blood is below a certain level. After the liver has been thoroughly examined for contraindications to surgical treatment, the vascular system should receive attention. Thrombosis of the portal vein and adhesions between the spleen and the walls of its bed are contraindications to splenectomy. Discussing 115 splenectomies performed by himself, he says that in the first fifteen operations he had an immediate mortality of 33 per cent. In the later cases the mortality fell to 7 per cent. As regards the late results of splenectomy for splenomegaly, he says that the hemorrhagic tendency is nearly the only danger that has to be feared. Of thirty-seven patients who were operated on, nine did not present hemorrhage, while the twenty-eight others had had hemorrhages before the operation, such as epistaxis and bleeding from the gums. Of the aforementioned nine patients, two had malarial hypertrophy, two had tumoral hypertrophy, one had kala-azar, one had leukemia and three had splenomegaly of unknown origin. The twenty-eight splenomegalies with considerable hemorrhages were for the most part of the type characterized by the presence of Gamna nodules. Of these twenty-eight patients, twenty-one remained free from hemorrhages, but the seven others had recurrences of hemorrhages. The late results of splenectomy are good, for the author observed 81 per cent of permanent cures. They were entirely free from those changes in the blood and in the capillaries which make the prognosis unfavorable.

Ascorbic Acid and Vascular Resistance.—According to Adant, the question of the relation of ascorbic acid to the vascular fragility is still a subject of controversy. Whereas some investigators observed that a diet in which the vitamin C supply is deficient produces an increase in the vascular fragility, others have been unable to corroborate this observation and could not detect a parallelism between vascular resistance and the ascorbic acid content of the blood. Since a review of the literature seemed to suggest that the mode of administration of ascorbic acid might be important, the author studied the influence of the intravenous injection and of the ingestion of ascorbic acid on the vascular resistance. The results obtained indicate that the mode of administration makes a difference in the action of ascorbic acid on the vessels. The intravenous injection of 100 mg. of ascorbic acid produces a rapid and strong but transitory augmentation of the vascular resistance. This action is exerted even in persons who are saturated with vitamin C. On the other hand, the ingestion of 300 mg. of ascorbic acid does not modify this resistance either in persons who are saturated with vitamin C or in those who have a vitamin C deficiency. Finally, if normal children, whose deficit does not exceed 2 Gm., are saturated with ascorbic acid by ingestion, the vascular resistance, measured on a day following the saturation, shows only a slight rise in five out of eighteen cases. This increase is too slight and too inconstant to be regarded with certainty as a consequence of the saturation.

Nontuberculous Purulent Axillary Pleurisy.—Clavelin and Sarroste report their observations on nine cases of purulent axillary pleurisy which they observed among a total of forty-nine nontuberculous pleural suppurations. They think that the anatomoclinical peculiarity of the localization, the relatively benign character and several diagnostic and therapeutic difficulties

of this process deserve emphasis. The disorder develops after an acute pneumopathy. It appears in two forms: the one chronic, aseptic, producing a low sound and often latent for long periods, a veritable roentgenologic discovery; the other one acute, usually due to streptococci and developing like a purulent pleurisy of the large cavity. The axillary localization of pleural suppurations appears after a limited cortical pulmonary focus. It is preceded by a phase of generalized pleural edema and it forms itself as the result of a defensive perifocal union of the pleural layers. The axillary pleurisy evolves afterward as a limited and closed pleural abscess until maturation. The older the process is, the thicker becomes the visceral pleura; in the chronic pleuritis it forms a shell which prevents absolutely all pulmonary expansion. The treatment of acute purulent axillary pleurisy consists in awaiting the period of maturation of the pleural abscess and in opening it at the sloping point by pleurotomy with costal resection. The sequels are slight, the results excellent. Chronic axillary pleurisy, on the other hand, justifies a thoracotomy, followed generally by pulmonary decortication. Although its evolution is less explosive than that of the acute form, its treatment is difficult and there frequently remain serious sequels.

Problem of Harmfulness of Endonasally Administered Medicaments That Contain Oil. A. Marum and M. Kleissner.—p. 565.

Protamine Zinc Insulin.—Constam gives a brief history of the development of the insulin preparations with prolonged action and then evaluates his own experiences and those of others with protamine zinc insulin. He shows that although hypoglycemic manifestations are less frequent after the administration of protamine zinc insulin than after ordinary insulin, they are more difficult to detect and more serious in their course. On account of the danger of hypoglycemic manifestations it is inadvisable to give large doses of protamine zinc insulin to ambulatory patients. Great precaution is necessary in applying experiences and dosages on hospital patients to ambulatory patients. Moreover, protamine zinc insulin should be given only to those patients whose intelligence, character and occupation give assurance that the regulations of the administration will be strictly followed. The patients and the members of their families must be acquainted with the different prodromal signs of a hypoglycemic shock as well as with the measures to be taken. They must know how to arrange the diet and how to handle the insulin syringe. The insulin dosage must be strictly adjusted to the metabolic condition, and for this reason daily control of the urine is necessary. Before great exertions, the quantity of insulin should be reduced and the intake of carbohydrate increased. Protamine zinc insulin should never be given more than once in twenty-four hours. In many cases it will make possible a reduction in the number of injections or a concentration of the insulin injections to the morning hours. In the most severe and extremely labile cases it is often impossible to reduce the number of injections, but it may prove feasible to regulate the strong fluctuations in the blood sugar and to limit the hyperglycemia in the morning. For patients who for years have been well adjusted to treatment with ordinary insulin a change to protamine zinc insulin is inadvisable, because, as has been pointed out by Bernard Smith, the regulatory mechanism of these patients has become completely adapted to the rapidly acting insulin. In conditions in which the insulin requirements change rapidly, such as injuries, intercurrent diseases and operations, ordinary insulin is used alone or in combination with protamine zinc insulin. The author concludes that the new insulin with the prolonged action has made the insulin therapy easier for many patients. However, the use of the new insulin has its limitations.

Differential Diagnosis Between Acute Appendicitis and Diseases of

Upper Segment of Urinary Tract. G. S. Donati.—p. 173.

Pneumococcal Peritonitis: Clinical Study. E. Forti.—p. 195.

Microscopic Studies of Gastric Wall Near Cancer.—Ruggieri studied, microscopically, nineteen cases in which the cardiac segment of the gastric wall was removed in the course of gastric resection for cancer. The author found cancer cells in the layers of the gastric wall as far as 7 cm. from the macroscopic periphery of the tumor, and pathologic alterations of the tissues of the wall as far away as 9 or 10 cm. He therefore advises wide resection. It is important that care should be taken in making the sutures, as the tissues are extremely fragile and their powers of self reparation are diminished.

*Gastric Chromoscopy with Neutral Red in Normal Infants and in Nutritional Disturbances in Infants. A. Ferro.—p. 269.

Infantile Acrodynia: Case. R. Dardani.—p. 291.

Syphilis in Mothers. M. Monacelli.—p. 295.

Gastric Chromoscopy in Infants.—Ferro studied the secretory functions of the stomach of fifty normal infants and of thirty who were suffering from nutritional disturbances by means of gastric chromoscopy and the chemical behavior of the gastric secretion in the course of the test. Most of the infants ranged in age from 1 month to 1 year. Only four in each group were older than 1 year. Chromoscopy was done during fasting, after administration of an intramuscular injection of 1 or 2 cc. of a 1 per cent solution of neutral red in sterile distilled water (according to the age and body weight of the infant). On appearance of the dye in the gastric secretion the infants were fed once on their original diet, whether natural, artificial or mixed. The gastric secretion was withdrawn before and thirty, sixty and 120 minutes after a feeding and the chemistry of the secretion was determined. The author found that the free and total acidity of the gastric secretion of fasting infants are low in the majority of cases. Hydrochloric acid appeared late in the gastric secretion after a feeding and in insufficient amount in thirty-five normal and in twenty-one infants with nutritional disturbances. The time of chromoscopy, which is the time which elapses between the injection and the appearance of the dye in the gastric secretion, varied between eight and twelve minutes in forty-five normal infants and between eleven and thirty-two minutes in eighteen patients. The dye failed to appear in the gastric secretion in five normal infants and in twelve patients. The age and the type of feeding, natural, artificial or mixed, did not have any influence on the results. The time of chromoscopy and the intensity of hydrochloric acidity were in relation to each other in only some of the cases of each group. The test was repeated after two weeks in eleven normal infants. The results were the same as those obtained in the first test in only three instances. The author concludes that chromoscopy can be easily and harmlessly used in infants but that it has no clinical value for secretory functions of the stomach. However, the results show that the secretory function of the gastric mucosa for dyes are diminished in nutritional disturbances in infants, as compared with those of normal infants.

*Treatment of Malarial Splenomegaly by Epinephrine (Ascoli's Method). S. Livierato.—p. 899.

Leptomeningeal Hemorrhage in Young Woman: Case. G. Dalla Torre.—p. 904.

Epinephrine in Malarial Splenomegaly.—Ascoli's treatment for malaria was reported in THE JOURNAL May 8, 1937, page 1065. It consists in intravenous injections of progressively increasing doses of epinephrine, which are administered daily until thirty injections have been given. Livierato treated seven

adults presenting malaria of the daily, tertian and irregular types of from two to fourteen years' duration. There was intense splenomegaly and anemia in all cases and the patients were in poor general condition. Treatment was discontinued by two of the patients. Treatment gave satisfactory results in the other five cases. The author thinks that the treatment is harmless. In some cases there is a transient intolerance but treatment can be continued without interruption. While the treatment is being taken the appetite and general condition of the patients improve, weight increases, the malarial skin tinge disappears, the blood improves and splenomegaly is progressively reduced. In the group of patients observed by the author at the end of the treatment the weight of the patients increased from 4 to 9 Kg., erythrocytes increased from 1,000,000 before treatment to 2,500,000 per cubic millimeter of blood after treatment. Hemoglobin increased from 20 to 40 per cent. The results of the treatment are permanent.

Semana Médica, Buenos Aires

- *Study and Treatment of Hereditary-Familial Neurologic Diseases with Predominant Lesions at Spinal Cord. R. Soto Romay.—p. 897.
Some Characteristics of Enlargement of Right and Left Ventricles. P. Cossio and R. Dambrosi.—p. 929.
Acute Postoperative Dilatation of Stomach. J. E. Igarzábal.—p. 936.
Embolism from Intramuscular Injection of Substances in Oil. I. R. Steinberg.—p. 945.

Hereditary Neurologic Diseases.—Soto Romay states that the various hereditary familial neurologic diseases with predominant lesions at the spinal cord are clinical forms of a process of degeneration of certain segments of the nervous system. The group of familial neurologic diseases with lesions of the spinal cord have many common symptoms and analogous anatomopathologic lesions. The author states that there are atypical and transitional forms between familial spasmodic paraplegia, progressive amyotrophy of Charcot-Marie type and Friedreich's hereditary ataxia. In the course of the disease the patients may show transformation of one type to another or the association of two or more atypical forms of the disease. The author reports three cases, in a mother and her two children. The three patients suffered from a combined form of spasmodic paraplegia, progressive amyotrophy and hereditary ataxia. In all three the factor of heredity and infection existed. The amyotrophy of the distal part of the legs as well as of the feet and hands was severe in the mother and in the oldest son, aged 13 years. The disease was of slow evolution in the mother, acute in the son and latent in the daughter, aged 7 years. The microscopic study of the amyotrophic muscle, which was taken by a biopsy, showed waxy degeneration of the muscular fibers, with loss of striation. There were proliferation of the sarcolemma nuclei, perivascular infiltration and proliferation of the interstitial tissue. The author reports satisfactory results of a combined treatment of vitamins and liver extracts. The evolution of the disease stopped and the patients gained some muscular force and control of the nervous symptoms. The author calls attention to the diagnostic value and significance of the contralateral Schaeffer sign, which is positive in acute hereditary neurologic diseases and shows involvement of the pyramidal segment. It was positive in the author's male patient.

Diagnostic Significance of Displacement of Pineal Body in Alterations of Intracranial Pressure. M. Ernst.—p. 224.
*Chronic Mastopathy Newly Considered. R. Wanke.—p. 234.

Abdominal Grip.—Uebermuth observed, in the course of a grip epidemic in the beginning of 1937, occasional cases of what he considered primary grip peritonitis. The observations in his own three cases and the review of recent literature suggest that primary grip infection of the peritoneum is a definite entity presenting a fairly-characteristic picture. The disease begins with vomiting, diarrhea, tenderness in the left lower half of the

abdomen, distention, arrest of fecal current and flatus, dry tongue, fast pulse and fever. A laparotomy reveals a diffuse peritonitis with a proffuse greenish-yellow slimy and entirely odorless exudate. Cultures from the exudate fail to reveal influenza bacilli. In one of the author's cases the cultures were entirely negative and in two hemolytic streptococci were grown. The intestinal loops are red, those of the terminal ileum presenting grayish-whitish deposits and areas of bluish-black discolorations due to subserous hemorrhages. The rest of the viscera show nothing of importance. There is in the beginning a leukopenia. The mode of infection may be hematogenous or enterogenous, with the point of origin in enteritis of the terminal ileum. The former type offers a worse prognosis.

Chronic Mastopathy.—According to Wanke, statistical studies show that the incidence of chronic mastopathy in unmarried women is no greater than in the married women. His own observations suggest that the neglect of a "natural function" is not the cause of the disease. Likewise not much, if any, pathogenic importance can be attached to too frequent functional activity of the breasts in oft repeated pregnancies and nursing, as is evident from the fact that women who have borne many children are seldom subject to this disease. The fecundity of women with mastopathy is only slightly inferior to that of women with normal breasts. Investigations thus far have thrown little light on the question of the fertility of a woman who has had mastopathy, although the author's personal observations suggest that women who have had mastopathy at the age of 30 or later are less likely to have children. Quantitative determinations of the excretion of the estrogenic substance in the urine of two patients demonstrated a striking diminution with a reversal of the normal curve, thus pointing to a profound disturbance in the estrogenic substance economy as the cause of the mastopathy. The condition bears a resemblance to gynecologic disorders only so far as the latter present the evidence of certain functional alterations of a vegetative kind (hypoplasia of the genitalia). The author stresses the fact that a simultaneous glandular cystic hyperplasia of the endometrium was never observed—further evidence that this condition is likewise caused by a disturbance of the estrogenic substance economy, in this instance of too much hormone. The treatment of mastopathy is determined primarily by the differential diagnosis based on the results of biopsy. Endocrine therapy brought about remarkable results in some and encouraging results in all the author's cases. Chronic mastopathy develops in all probability on the basis of ovarian insufficiency.

Test for Corpus Luteum Hormone.—Duyvené de Wit points out that formerly the corpus luteum hormone was demonstrated by means of the changes it elicits on the uterine mucosa of rabbits during apparent pregnancy. The two test methods most widely used for this purpose were those of Allen-Corner and of Clauberg. However, these tests have the disadvantage that they require a comparatively long time (six days) and detect only comparatively large quantities of hormone. The author, having observed that the female minnow is highly sensitive to the corpus luteum hormone (progesterone), decided to use minnows as a test subject. He found that the ovipositor of minnows shows an increase in length after a comparatively small quantity of progesterone has been added to the water of the aquarium containing the minnows. The growth persists for from five to seven hours and is macroscopically visible. Within certain limits the growth of the ovipositor is proportional to the amount of hormone added. Thus the test makes possible the quantitative demonstration of progesterone. It detects

quantities as small as from 10 to 20 micrograms. The test is not only rapid but also economical. The minnows can be used repeatedly. Discussing the specificity of the test, the author says that the growth of the ovipositor in minnows has been used as a test for other sex hormones for those of the estrogenic type and for those of the androsterone group. Between the time that the hormone is introduced into the aquarium and the onset of the growth of the ovipositor, a certain time elapses. This time is designated as the latent period. If hormones of the estrogenic type are added the latent period is ten or twelve hours, but if hormones of the androsterone or progesterone group are added the latent period is one hour. It is important that fifty times more androsterone than progesterone is required to produce the same reaction. The author also gives a definition of the ovipositor unit; it is equal to one eighth of the distance between the insertion and the terminal rim of the extended organ.

Adhesions Following Pleurisy with Effusion.—Leifer discusses the correspondence between the type of inflammatory processes in pleurisy with effusion, of tuberculous origin, and the extent of the adhesions formed. The more severe the pleuritic inflammations the more copious the effusion, and the longer the latter remains within the cavity the more it becomes inspissated until fibrinous layers, the foundation of adhesions, are formed. If the tuberculous foci are present in the pleura the inflammatory and effusive processes will be greatest; if the influence is less direct (through bronchial pneumonia or the bronchial lymph nodes) the pleurisy will be less severe. The author does not agree with Illig and others that the formation of adhesions has a favorable immunobiologic influence on the tuberculosis and is not to be combated. Adhesions may have definitely unfavorable consequences: circulation may be impaired by the unilateral constriction of the thoracic organs, the crippled lung may show greater susceptibility to bronchopneumonia, and the presence of adhesions may make it impossible to perform a needed pneumothorax. Formation of adhesions is best minimized by frequent punctures which counteract the tendency of long standing effusion to thicken into fibrinous layers. The author made clinical and roentgen follow-up studies in fifty of 150 cases in which repeated punctures were done. Slight adhesions had formed in forty-one cases, adhesions were almost completely lacking in four and they were extensive in only five. The author concludes that repeated puncture, even if it cannot prevent adhesions, can limit their extent.

*Fluctuations in Creatine and Creatinine Content of Blood During Athletic Training. P. Backman, V. Pirilä, T. Raekallio and I. Väänänen.—p. 304.

Creatine and Creatinine During Athletic Training.—Backman and his associates describe studies on the fluctuations in the creatine and creatinine content of the blood of four persons who underwent intensive training, which involved great muscular exertion. It was observed that, as regards the creatinine balance, the four persons represent two different types:

In two (B and D) the creatine balance was sensitive, for it reacted rapidly and strongly; whereas in the two others (A and C) it was more stable, so that the changes were weaker and slower. The authors think that this difference might be related to the difference in the body structure, for A and C were strong bodied, whereas B and D were of a rather slight build. In all four persons, a wavelike periodic fluctuation could be observed in the basic value of the total creatinine. In the two persons of the first type the periods were short; in those of the second type they were long. In the persons of the first type there were periodic changes also in the basic value of creatine; the direction of the change (increase or decrease) was the same as in the basic value of the total creatinine, so that fluctuations in the total creatinine were determined chiefly by the fluctuations in creatine, whereas the basic value of creatinine showed only few quantitative changes. In the second type of person the basic values of the creatine as well as of the creatinine changes without continuity. The basic value of the total creatinine reached its maximum rapidly in the persons of the first type but after a prolonged rest in the persons of the second type. In the persons of the first type its value was considerably higher before the beginning of the training than was the case in persons of the second type. In all four persons (more in the first than in the second type) the total creatinine and creatine values decreased during the individual exertion when the basic values were on the increase and they increased when the opposite was the case.

*Ascorbic Acid Content of Human Milk During Summer and Winter. H. Winkler and E. Heins.—p. 148.

Ascorbic Acid Content of Human Milk.—Following a review of reports in the literature on the vitamin C requirements of nursing mothers and their nurslings, Winkler and Heins report their own investigations on the seasonal fluctuations of the ascorbic acid content of human milk. Summarizing their observations, they say that the ascorbic acid (vitamin C) content of human milk increases from the first to the fourth or fifth day of the puerperal period, parallel to the transformation of colostrum into milk, colostrum having lower ascorbic acid values than does milk. During the remainder of the puerperium, the ascorbic acid value stays the same. In the course of the summer months it remains at about the same level regardless of a prolonged lactation. The ascorbic acid content of breast milk during the summer months was found to be between 4.6 and 6.6 mg. per hundred cubic centimeters. Usually the values were around 5.7 mg. per hundred cubic centimeters. The winter values were about one third lower than the summer values. They fluctuated between 2.9 and 5.2 mg. per hundred cubic centimeters. The mean was 4.1 mg. per hundred cubic centimeters. By the parenteral administration of ascorbic acid to nursing mothers, it was possible to increase the ascorbic acid content of their milk to 9 or 10 mg. per hundred cubic centimeters. This increase was induced more readily during the summer than during the winter. After the parenteral administration of ascorbic acid was discontinued, its content in the milk gradually decreased. During the winter months, the authors observed a deficit of vitamin C in nursing mothers which was not present during the summer months. They think that the presence or absence and the extent of the vitamin C deficit is largely dependent on the diet and on the season. This also explains the difference in results obtained by various investigators. They recommend that during the winter (November to April) pregnant and nursing women should receive vitamin C in addition to their food, so as to avoid a C hypovitaminosis. During the summer months (May to October), however, the vitamin C requirements will usually be met by a suitable diet.

Effect of Pancreas on Mortality of Operations on Biliary Tracts. F. Bernhard.—p. 920.

Appendicitis, Ileitis and Inflammatory Ileocecal Tumors.—Låwen states that microscopic features of the entity he described in 1914 under the name of fibroplastic appendicitis are identical with those of terminal ileitis described in 1932 by Crohn, Ginzberg and Oppenheimer. He had stated in his description that fibroplastic appendicitis may involve the cecal wall and the terminal portion of the ileum and thus lead to a secondary terminal ileitis. The extensive literature on the subject of the etiologic relationship of the appendix to terminal ileitis permits the separation of the patients into three groups. In group 1 belong patients presenting at operation a terminal ileitis without the involvement of the appendix. In group 2 belong patients in whom the appendix had been removed a shorter or a longer time before the operation and in some of whom at least the appendix could not have been the primary cause. In group 3 belong patients in whom there are found inflammatory changes in the appendix in the course of an operation for chronic stenosing terminal ileitis. These alterations, however, not infrequently give the impression of being secondary rather than primary. The author concludes that the tumor forming chronic stenosing ulcerative or nonulcerative terminal ileitis and fibroplastic appendicitis and the analogous disorders of the ascending colon present an identical microscopic picture. They represent the same type of inflammation with a different primary localization. In a number of cases the relationship between terminal ileitis and the inflammation of the appendix cannot be demonstrated. There are cases of ileitis in which it is possible to establish the etiologic relationship to an acute appendicitis and a chronic terminal ileitis which had developed at a later period. A primary ileitis may involve the cecal wall, its mesentery and the appendix itself. The fibroplastic disease of the intestinal wall developing from the intestinal mucosa and involving the terminal ileum, the cecum and the ascending colon and giving rise to typical clinical entities is probably the same process as diverticulitis described by Graser, the postoperative chronic inflammatory tumors of the omentum described by Braun, the abdominal wall tumor described by Schloffer and possibly the peculiar, nonspecific chronic fibrous encapsulating peritonitis.

New Device for Continuous Vaginal Irrigation. F. Hoff.—p. 876.

Diagnosis of Ovarian Dysfunction.—After pointing out that the great value of the microscopic examination of the endometrium of patients with ovarian dysfunction has been recognized by a number of authorities, Sommer cites some of the methods that have been recommended for this purpose. He says that at the clinics in Kiel and in Leipzig the so-called streak curettage has been found helpful. Reifferscheid uses a special streak curet, but the author simply uses a small curet. The procedure can be made without anesthesia. It requires merely a dilation up to Hegar 6. The curet is pushed up to the fundus, is pressed lightly against the anterior uterine wall and is drawn downward. Observations in the clinic and during ambulatory consultations revealed that even the repeated application of the streak curettage involves no injury to the patient. On the basis of case histories the author shows that the streak curettage provides valuable information about the ovarian function and thus helps in deciding the best treatment and in forecasting the probable outcome of the disorder. He

emphasizes, however, that for the determination of the presence or absence of a malignant tumor the streak curettage is inadequate.

Ocular Tension and Pregnancy.—Patat says that in a previous report (two years ago) he and his collaborator related observations on 151 cases in which studies were made during the different phases of pregnancy, delivery and the puerperium. Comparative tests on nonpregnant women of the same age revealed that the ocular tension of pregnant, parturient and puerperal women is usually reduced. In those women in whom the values were definitely reduced during pregnancy, the author renewed the test one or two years after delivery. In this paper he gives a tabular report of twenty-seven women who were reexamined. The table clearly demonstrates that the ocular tension of the same person is usually lower during the processes of gestation than is the case one or two years after delivery. Discussing the possible cause of the ocular hypotension during pregnancy, the author suggests first that the acidosis of pregnancy might play a part, pointing out that a lowered ocular tension has been observed during other processes that are accompanied by acidosis, such as diabetic coma. Other factors that might be involved are reduction in the osmotic pressure, chemical changes in the blood or changes in the endocrine function. A complete explanation has not been found as yet.

- Studies on Objective Factors of Hunger and Satiety. J. Monauni.—p. 159.
*Hypophysis and Water Exchange. P. Wermer.—p. 189.

Hypophysis and Water Exchange.—Wermer discusses recent advances in the knowledge of the pathogenesis of diabetes insipidus, giving special attention to the significance of the anterior lobe of the hypophysis in the pathology and physiology of the water exchange. After pointing out that the significance of the anterior hypophysis in diabetes insipidus was indicated two decades ago by the observations of von Hann, he cites recent observations, particularly by American authors, which likewise indicate that the anterior lobe of the hypophysis does play a part. On the basis of these reports in the literature and of his own experiments and observations, he reaches the conclusion that a substance with strong diuretic action can be extracted from the anterior lobe of the hypophysis. This substance is contained in that fraction which also contains the growth hormone. There are two types of diabetes insipidus: that caused primarily by the posterior lobe of the hypophysis and that caused by the anterior lobe of the hypophysis. In both types there exists a disproportion between the diuretic hormone of the anterior lobe of the hypophysis and the anti-diuretic hormone of the posterior lobe of the hypophysis. The deficiency in secretion of the posterior lobe of the hypophysis may be caused by a destruction of the posterior lobe or by an impairment of its innervation. An excess of hormone of the anterior lobe of the hypophysis may be caused by a basophil adenoma or during pregnancy by a transformation of the hypophysis which is elicited by the genital glands. Destruction of the anterior lobe of the hypophysis in the presence of an unimpaired posterior lobe produces oliguria; however, if it is accompanied by destruction of the posterior lobe, the development of diabetes insipidus is prevented.

Chemotherapy of Sepsis. L. I. Gifter.—p. 209.

Aplastic Anemias.—The great majority of blood diseases may be regarded, according to Rakochi, as a reaction on the part of the hemopoietic organs to various irritants. Pernicious anemia is one of the types of reactive processes. Sepsis not infrequently appears to be the cause of such reactions, capable of producing alterations in the blood resembling those of per-

pernicious anemia. Such cases are to be regarded as a syndrome of pernicious anemia accompanying sepsis. As is well known, liver therapy is most effective in this type of anemia. Its effect in other pernicious anemia syndromes is not nearly so reliable. There exist a number of syndromes of pernicious anemia with known etiology, such as anemia of pregnancy, of helminthiasis or of sepsis. Pernicious anemia may run its course as a regenerative type, either hypoplastic or aplastic. Aplastic anemia may begin as such or it may develop from a regenerating type. The etiologic factors are variable, sepsis being among the more frequent. Hemolytic processes may be present or absent, depending on the etiologic causes. The author regards aleukia as a general concept. Various etiologic factors may give rise to a typical picture of aleukia; among these sepsis is a frequent cause. Cases of aleukia associated with the involvement of erythropoiesis belong in the group of aplastic pernicious anemias.

Nathan's Reaction in Tuberculosis.—Braginskaya reports results with the use of a test proposed by Nathan and Kallos in 1931. The technic of the test is as follows: A piece of gauze 1 cm. in diameter was moistened in old tuberculin and applied to the healthy skin on the flexor surface of the forearm. The edges were secured to the skin by some adhesive substance. Clear bouillon was used for control. The dressing was removed twenty-four hours later and the reaction was observed for the next five or six days. When positive, the typical reaction is characterized by the appearance of small vesicopapular lesions on a normal or somewhat hyperemic base. The lesions begin to disappear from two to three days later. On the basis of experience in 184 patients, the author concludes that the reaction of Nathan may be included among the sensitive and specific reactions in tuberculosis. Both general and focal reactions were absent. Positive reaction was observed in active cases only. The reaction is more pronounced and its incidence is greater in cases of tuberculosis of the skin, although it gives a considerable percentage of positive reactions in tuberculosis of other systems. The experience of the author is not in agreement with the conclusions of Nathan and Kallos, who consider that the test has a selective affinity for tuberculosis of the skin. The test in children does not differ from that in adults. The reaction may be negative in grave cases of tuberculosis accompanied by marked exhaustion, as well as in the stage of recovery.

*Fever Therapy of Gonorrheal Conjunctivitis by Means of Intravenous Injection of Cholera-Typhoid Vaccine. H. G. Hofstee.—p. 2028.

Therapy of Gonorrheal Conjunctivitis.—Hofstee says that whereas in the Netherlands gonorrheal conjunctivitis is practically disappearing, the condition is still comparatively frequent in the Dutch East Indies. He discusses observations on patients with gonorrheal conjunctivitis who came for treatment to the Wilhelmina Hospital in Bandung (Java). The material comprises in all about 900 eyes that were treated in the years between 1929 and 1936. The majority of patients were adults, but there was also a considerable number of infants with gonorrheal conjunctivitis. The treatment consisted in intravenous injections of 0.1 cc. of cholera-typhoid vaccine or in intramuscular injections of milk or in measures such as irrigations with solution of potassium permanganate and treatment with silver nitrate. Approximately 50 per cent of the patients with gonorrheal conjunctivitis had a more or less severe involvement of the cornea. The author thinks that this is partly due

to the fact that the patients are hospitalized rather late, and partly to the poor condition of the cornea as the result of mixed infections (trachoma) and (latent) A avitaminosis. Discussing the efficacy of the different treatments, the author says that the injections of cholera-typhoid vaccine effect cure on the average in nine days, the milk injections in eleven days and the other measures in twelve days. He thinks that the intravenous injection of typhoid-cholera vaccine is the best form of fever therapy for gonorrheal conjunctivitis.

*Nervous Complications in Epidemic Parotitis: Meningoradiculitis Basalis Parotidea. K. G. Fuhrmann.—p. 159.
Recurrent Colic After Gallstone Operations. S. Müller.—p. 168.

Leukosis.—According to Engelbreth-Holm, investigators agree that leukoses in animals, especially in chickens and mice, are analogous to leukoses in man and that leukoses are to be regarded as tumor formations. The observation of several cases of lymphatic leukoses in closely related persons suggests the possible presence of a hereditary constitutional factor. Investigations in inbred mice clearly show hereditary factors to be most important in the origin of leukoses in animals. The receptivity of mice to implanted leukoses depends on hereditary factors transmitted as a dominant characteristic; the occurrence of spontaneous leukoses depends in part on hereditary dispositions of a far more complicated kind and does not depend on a dominant characteristic. The author states that while leukoses, at all events those with a rapid course, have by some been assumed to be due to infection, undoubtedly a complicating secondary infection often sets in in true leukoses with a rapid course; a positive result on cultivation of bacteria from the blood affords no evidence as to the infectious nature of leukoses. At present the theory of a virus as the cause of leukoses in mammals is considered one of the most plausible theories, but it is not established. Investigations have shown that the tumor-producing viruses are not independently living organisms. The greater frequency of leukoses in man in winter than in summer has not yet been explained, and similar unexplained conditions prevail in chicken leukoses. While recent investigations have given the clinic new and valuable adjuvants for the diagnosis of leukoses, therapy continues to be only palliative. Stephens and Lawrence propose treatment with doses of arsenic, increasing to beginning intoxication and then with continued sub-toxic doses. There is no recent confirmation of the reported improvement on treatment with ascorbic acid. Irradiation does not prolong the patient's life but leads to significant improvement in the condition.

Epidemic Parotitis.—In Fuhrmann's case the epidemic parotitis was accompanied by a defined meningitic lesion localized to the base of the cerebrum. He advises neurologic examination in all infections which often give benign meningitis. In later neurodisturbances the history then allows establishment of the pathogenesis in radiculomeningitis and circumscribed serous meningitis and perhaps also in the frequent cases of "changes in the spinal fluid," in which the subjective symptoms do not point to the nervous system or merely suggest the clinical picture of "neurasthenia" or "slight depression," and the most careful objective examination reveals no sign of organic nervous disorder. Because of the tendency in epidemic parotitis to nervous complications, especially benign, often latent meningitis, he would advise examination of the spinal fluid in every case of epidemic parotitis.

SOME UNSOLVED PROBLEMS OF TUBERCULOSIS

JAMES ALEXANDER MILLER, M.D.
NEW YORK

Physicians are all aware of the great progress in knowledge concerning tuberculosis which has occurred since the discovery of the tubercle bacillus in 1882. This, combined with the further recognized fact that there has occurred a notable decrease in the mortality and morbidity from tuberculosis in the greater part of the civilized world, has led to a feeling of satisfaction which is based on the assumption that the problems of this disease have been solved and that, in consequence, tuberculosis is in a fair way to be under definite and permanent control.

A critical analysis of the situation, however, reveals the somewhat disconcerting fact that while the very extensive researches have undoubtedly greatly increased knowledge, they have at the same time raised up many previously unsuspected problems concerning which there exist uncertainty and wide differences of opinion.

As some of the still unsolved problems concern the fundamental concepts of the pathogenesis and epidemiology of the disease, and as permanent control of tuberculosis depends on the soundness of such concepts, it seems desirable to review some of the disputed questions in the interest of progress in thinking, even though it be at the expense of complacency.

When one begins to look for them, one finds so many of these problems that it is impossible at this time to attempt the discussion of more than a few of those which are of especial interest and importance.

INFECTION AND CONTAGION

For centuries laymen have believed in the contagiousness of tuberculosis. Quarantine against it was established in Naples in 1751 and in Spain in 1782. Laënnec in 1817 noted the fact that nurses in contact with patients with phthisis rarely acquired the disease, although he did note that under certain conditions the disease might be communicable. Villemin, on the other hand, in 1853 based his notable animal experiments, which first proved the infectiousness of tuberculosis, on the observation that human phthisis was apparently communicable under crowded and untoward living conditions. In 1873, however, the elder Flint¹ wrote: "The doctrine of the contagiousness of the disease has now as hitherto its advocates, but the general belief of the profession is in its non-communicability."

Then came the discovery of the tubercle bacillus by Koch and Baumgarten in 1882, and as the enthusiasm engendered by the new knowledge of bacteriology was at that time in full flood it was natural that the profession and the laity alike should include tuberculosis with the other bacterial diseases which are communicable and contagious.

Thoughtful students, however, became increasingly impressed by the notable differences in the behavior of tuberculosis as compared with other infections. No one longer doubted that it was infectious or that the infection was communicable, but there were many inconsistencies in the relationship between the secondary phthisis and the primary source of infection.

Tuberculin surveys (Hamburger and Monti) a generation ago demonstrated that tuberculous infection was an almost universal phenomenon in large cities.

Postmortem studies (Naegeli, Burkhardt, Scheuermann, Huebschmann, Pagel) showed that in the overwhelming majority of adults there existed residues of a primary infection and also secondary lesions, especially in the lungs. While the numbers so infected are definitely less now than at the time of these original studies, it is still true that a large majority of all people are infected and yet only 1 or 2 per cent of adults contract phthisis.

It thus became obvious that other factors besides infection must enter into the problem to explain why disease develops in some persons and not in others.

RESISTANCE

Numerous clinical as well as experimental observations (Koch, Roemer and others) established the fact that the body offers an astonishing degree of resistance to its invasion by tubercle bacilli.

That in some instances this resistance is natural, constitutional or inherited is evidenced by the fact that many young children intimately in contact with tuberculous infection not only do not contract the disease but may even remain uninfected, as indicated by the lack of reaction to tuberculin. In several recent reports on extensive studies of a large dispensary material, Bezançon² emphasized that 18 per cent of children living in an infected environment do not react to tuberculin. Similar observations were made in an excellent epidemiologic study in a French village by Van den Eeckhout,³ who obtained in 11 per cent of over 500 children a negative reaction to tuberculin in spite of definite exposure.

From the Tuberculosis Service of Bellevue Hospital.

Read before the New York County Medical Society, May 23, 1938.

1. Flint, Austin: Practice of Medicine, Philadelphia, H. C. Lea, 1873.

In the great majority of instances, however, the resistance appears to be acquired and dependent on a previous and usually non-disease-producing infection. In previously infected persons either no actual disease occurred or, if it did, it was definitely altered into a chronic localized disease usually situated in the lungs, i. e., chronic phthisis.

In contrast to these cases the differences in the behavior of the disease in noninfected soil (infants and virgin races) were most striking. Here the tuberculosis was an acute, rapidly disseminating infection throughout the body, with no tendency to localization. The situation was well summarized by Bushnell,⁴ in 1920, as follows:

The belief that consumption is not infectious was based upon an enormous experience, but very naturally seemed erroneous when the infectious agent became known. The study of many years was required to show that the belief contained an element of truth, that consumption is not infectious for those who have already a tuberculous infection, even though it be occult.

The error of our fathers lay in failing to appreciate the fact that consumption, though indeed not infectious for the civilized adult, was sowing beautifully on every side the seeds of death for the child unprotected by a previous infection with tuberculosis. The error of modern times is to deny the protective influence of tuberculous infection against renewed infection from without. Thus is solved the riddle of the centuries. Our fathers saw one side of the shield, we have concentrated our attention too much on the other.

That this explanation, however did not completely "solve the riddle of the centuries" was evidenced by the fact that many previously uninfected persons escaped even when exposed and that many previously infected persons in the course of time contracted active phthisis.

For some of those in the first category the explanation of natural resistance is advanced. That this natural resistance may be inherited, not as specific resistance itself but as an increased resistance in the children of those who have acquired resistance, is a plausible theory recently supported by Doerr⁵ in spite of the fact that it runs counter to the generally accepted biologic law of the nonheritability of acquired characteristics. That it may be an inherent constitutional quality not specifically defined is held by many, and it appears certain that much will be heard in the near future concerning constitutional factors in tuberculosis as well as in many other diseases.

In both categories, persons primarily infected and those uninfected, the quantity and the frequency of infection appear determining. Even in the susceptible persons an insufficient and infrequent dose of infection will not produce disease, while in those comparatively resistant because of a previous infection, a sufficiently large and frequently repeated dose will overcome any such resistance. That this acquired resistance may be enhanced by the cumulative effect of many repeated small infections is evidenced by the behavior of certain groups in which such infections have occurred; e. g., the Jews in Europe. In these groups, not only is the mortality low but when the disease occurs it is usually of a chronic, nonprogressive type. That a considerable amount of such resistance may be acquired within two generations has been shown by Ferguson's⁶ careful study of a Canadian Indian tribe.

That this acquired resistance may be lost or seriously impaired has been equally well demonstrated. Evidence is accumulating that somewhat frequently sensitiveness to tuberculin may be evanescent when the infection is slight and may disappear when latent lesions become entirely healed. In such cases, while the infection does not behave like that in virgin soil, there is a diminished or altered resistance to reinfection. It is well known that resistance to tuberculosis may be impaired during certain infectious diseases (e. g., measles) or because of other unfavorable factors (such as malnutrition, the changes of puberty, pregnancy, or general economic and social stress) and that reinfection under such conditions is more likely to result in disease.

In general there is considerable evidence that resistance, both natural and acquired, has an important role in modifying the liability to disease after exposure to infection.

THE PATHOGENESIS OF PHTHISIS

My discussion now brings me to one of the most actively debated questions concerning tuberculosis: How does phthisis develop? Is it caused by direct contact with persons in the infectious stage through the inhalation of bacilli, or is it dependent on the activation of latent foci caused by the previous mobilization of bacilli to the lungs from the original primary lesion due to a previous, often remote, first infection?

The lines are fairly well drawn between physicians who believe in the exogenous origin and those who hold that evidence is in favor of the endogenous origin.

At first glance the first hypothesis, of direct cause and effect, appears plausible, and the early studies of Cornet and Pfluegge on the possibilities of droplet and dust modes of infection, respectively, aided in the crystallization of this theory. In recent times Aschoff⁷ and Puhl have supported this contention and claimed the possibility of the accurate pathologic recognition of characteristic foci of exogenous reinfection; this possibility, however, has been disputed and apparently disproved by Loeschke,⁸ Pagel⁹ and Grethmann.¹⁰

In this country Opie¹¹ has been the outstanding exponent of this theory, basing his opinion on his extensive epidemiologic and statistical studies. His main conclusions on this point, as indicated by his various reports, may be briefly summarized as follows:

1. Phthisis is produced by superinfection (exogenous reinfection) or by first infection of the lungs in adolescent or adult age.
2. Phthisis is a disease spread particularly by household contagion, which is even more dangerous to adults than to children.
3. As the severity of the disease is proportionate to the intensity and the prolongation of contact, the differences in dose of infection explain the individual variations in the disease.

Any conclusions based on such extensive studies as those of Opie deserve the most serious consideration. Yet a number of questions have been raised against his conclusions:

1. Why, if the inhalation of bacilli causes the disease, are not evidences of numerous such areas seen? As a

matter of fact, instances of the existence of more than one original primary infection are extremely rare.

2. Why, when the undoubted inhalation lesions of first infection are practically invariably in the middle or peripheral zones of the lungs, are the lesions of phthisis so regularly in the apical regions?

3. What mechanism serves to direct the subsequent infection away from the obviously direct route taken by the first infection, up to a region so difficult of access?

4. It having been proved that only a minimal amount of infection can reach the terminal bronchi and alveoli and that such minimal doses rarely if ever produce progressive phthisis, if the dose is the determining factor are not the possibilities of large doses reaching any particular area much greater by spread from the latent lesions through the lymph and the blood stream than by inhalation?

5. It is known that the primary inhalation lesion in the lung rarely progresses directly to phthisis. Why should the presumed subsequent inhalation lesions behave so differently?

6. It has been definitely proved that in the great majority of adults there often exist, in addition to the primary lesion, numerous secondary lesions, most regularly in the apexes of the lungs, and that these lesions harbor viable tubercle bacilli for an indefinite number of years. Can these apical lesions be ignored as the origin of apical phthisis?

7. Granted that active pulmonary disease is much more frequent under conditions of intense and prolonged contact, is there not some other explanation possible than that of the production of new direct inhalation lesions?

Physicians who are convinced of the validity of these objections to Opie's conclusions are advocates of the theory of the endogenous origin of phthisis. In the past decade and more their number has proved to be very large and includes pathologists and clinicians in many countries.

In general it would appear that the majority of careful students of tuberculosis now accept this explanation of the usual origin of phthisis and either reject the possibility of its origin from direct exogenous reinfection altogether or recognize its possibility as a comparatively rare exception to the rule.

Endogenous Phthisis.—The sequence of events in the development of phthisis from endogenous sources of infection was first most logically presented by Ranke. Beginning with the pathologic conception of the primary complex, with its pulmonary and lymphatic poles, as first discussed by Parrot, Kuss and Ghon, Ranke described the postprimary dissemination from the lymphatic pole through the lymph and blood stream, with numerous deposits in various organs but especially in the apical and subapical zones of the lungs, and from these foci the development when the conditions are favorable of active organic phthisis. From this point the disease spreads no longer by the lymph and blood stream but by the air passages, the so-called method of bronchogenic spread. This mode of development from such latent inactive lesions has been designated by Ulrici¹² as "exacerbation phthisis." Its occurrence depends either on the lowering of resistance, as I have already indicated in my discussion of that subject, or on the exacerbating effect of considerable exposure to

new exogenous infection in developing a hypersensitiveness, as will be discussed later in the consideration of the problem of allergy. This has been designated by Redeker¹³ as the "trigger action" of superinfection.

It is to be emphasized that these latent foci are a most common finding by modern radiographic methods, that while they always represent potential possibilities for phthisis they are not in themselves phthisis and that, in fact, a very small percentage of them ever do develop into phthisis. Consequently, while they deserve recognition and periodic radiographic reexamination and indicate supervision of the subject, they by no means always need active treatment. The discovery of the foci and the proper management of the subject present one of the great unsolved problems of tuberculosis today.

Another important problem is that of the danger of infection to young adults who have previously been uninfected. The interest in this group has been largely concentrated on the problem of nurses and physicians.

Heimbeck and Wallgren in Scandinavia and Edwards in England have made special studies of these groups, and in this country the work of Myers and his associates has received wide attention. Myers¹⁴ stated:

With approximately 100 per cent of the students contaminated with tubercle bacilli during the course of their training, one must expect the incidence of demonstrable lesions, which subsequently develop, to be much higher than in a general population, in which not more than from 10 to 30 per cent of the young adults have been infected with tubercle bacilli. Where actual observations have been made this has been found to be true.

He said further:

While we have been priding ourselves over the marked decrease in the incidence of positive tuberculin reactors among children and young adults throughout most of this nation, we have tolerated a situation that has permitted students of nursing and medicine to become infected with tubercle bacilli at a rate no less than probably existed in the general population a century ago.

That this situation represents to him a real tragedy is evidenced by his statement:

We know that once the primary complex has been allowed to develop, as manifested by a positive tuberculin reaction, there is no treatment of any avail; that is, the condition is beyond recall. Immunity does not develop sufficient to destroy the tubercle bacilli. No treatment that we know, such as long periods of strict bed-rest or even collapse therapy, destroys the tubercle bacilli in the lesions of the primary complex. Moreover, we have no practical method of permanently desensitizing the tissue of such persons.

Heimbeck and Wallgren are not so pessimistic and have been experimenting with BCG vaccination in these groups. A report on the ultimate results of their experiments will be interesting. Possibly, as will be discussed in my consideration of allergy, a better appreciation of those who are more liable to serious effects from considerable exposure to infection may some day be obtained from studies of their various allergic states, and possibly in this way provision may be made for their more adequate protection.

13. Redeker, F.: Das Problem der Reinfektion vom klinischen Standpunkt aus; in Engel, Stefan, and Pirquet, Clemens: *Handbuch der Kinder-tuberkulose*, Leipzig, Georg Thieme 1:261, 1930.

14. Myers, J. A.: The First-Infection Type of Tuberculosis, *Am. Rev. Tuberc.* 34:317 (Sept.) 1936. Myers, J. A.; Diehl, H. S.; Boynton, Ruth E., and Trach, Benedict: Development of Tuberculosis in Adult Life, *Arch. Int. Med.* 59:1 (Jan.) 1937; The Latent or Smoldering Stages in Tuberculosis, *Am. Rev. Tuberc.* 36:355 (Sept.) 1937; Tuberculous Pulmonary Infection in Hospital Personnel, 33d Annual Meeting of the National Tuberculosis Association, 1937, p. 309.

12. Ulrici, H.: Die Lungentuberkulose der Erwachsenen im Gesamtbild der Tuberkulose, *Bull. Internat. Union Against Tuberculosis* 13:477, 1936.

Apparently, although he has not categorically so stated, Myers believes in the endogenous spread of lesions to the lungs from the primary complex but considers such lesions in the same serious category as definite phthisis. Apparently also he believes that the only real solution eventually is a community not only completely tuberculin negative but free from opportunities for infection.

To many, as to Bushnell, this seems hardly a feasible objective and moreover one that is fraught with dangers if the process of acquiring racial resistance through habituation to occasional small doses of infection is interrupted. Also, many do not share Myers' great dread of first infections, for the reason that only a small percentage of them ever develop into phthisis and that for many persons they apparently afford a considerable measure of protection against the practically unavoidable occasional contacts with heavier doses which occur in modern urban communities, as well as against the even heavier doses that may arise from the intermittent endogenous discharges of bacilli from existing lesions.

While Opie expressed agreement with Myers' concept of the special danger from first infections in young adults, other workers, such as Schroeder¹⁵ and Herlitz,¹⁶ have come to opposite conclusions.

Under such conditions of reasonable doubt concerning the dangers involved it would appear desirable that further studies should be made before such sweeping conclusions as those of Myers are reached.

Summarizing the present state of knowledge of the problems of infection, it may be stated that:

1. Infection is transmitted from one human being to another.
2. Opinion differs as to whether this infection is the direct cause of phthisis in the lungs, but the majority of workers now believe that it is not.
3. The development of phthisis requires something more than infection.
4. This factor in the majority of cases is the exacerbation of preexisting lesions.
5. The exacerbation may be caused by superinfection from the outside but is more especially dependent on variation in the resistance of the body to the infection, whether it is exogenous or endogenous.
6. There exists a long period of latency before the lesions become exacerbated, and in the large majority of cases they never develop into phthisis or clinical disease.
7. Differences of opinion exist as to the danger of first infection in adults as compared with that of the exacerbation of previously existing lesions.

ALLERGY AND ANERGY

The practical meaning of allergy and anergy with regard to tuberculosis is the sensitiveness or lack of sensitiveness to tuberculin.

In my discussion of acquired resistance I noted the effect (allergy) of the changed reaction following infection on the behavior of the tissues to subsequent infection and that this change apparently affords a certain degree of protection against the development of disease. As this is an immunobiologic reaction it has led to considerable discussion and confusion of thought concerning allergy and immunity. It is now a generally accepted fact that in the human being there is no true

immunity to tuberculosis, that a sufficient dose of infection will always cause disease but that, on the other hand, there is a great variation between persons as to the dose necessary to produce this result. It is also known that allergy and immunity are distinct characteristics although they have a definite relationship to each other. This has been expressed by the formula that allergy is associated with a relative immunity. As this is by no means always true, if by immunity one means protection against disease, and as the whole subject is a very complex one by no means completely understood, it would appear wiser and more nearly in accord with known facts if, at least in clinical thinking, one used the term resistance and discarded the term immunity altogether.

The Significance of Reactions to Tuberculin.—The question concerning allergy which clinicians wish to have answered is What is the significance of a positive or a negative reaction to tuberculin in a given case, and if the reaction is positive what significance may be attached to a mild as opposed to a marked reaction? Epidemiologists are greatly interested also in the mass significance of the results of tuberculin surveys, now very numerous, which show such varied results in different communities. A positive reaction to tuberculin certainly indicates a previous tuberculous infection. A negative reaction, or a state of anergy, as Hayek termed it, may or may not indicate absence of such infection. In infants and young children a negative reaction is practically positive evidence of lack of such infection. This is essentially true of older children and adults in nontubercularized communities (virgin soil).

It has long been well known that allergy is lost in the terminal stages of tuberculosis, during some of the infectious diseases (measles) and also during depressed physical conditions from various causes. Also, it is definitely known that sensitiveness to tuberculin disappears when tuberculous lesions become completely healed. It is less generally recognized that after a considerable number of mild infections the resulting allergy is evanescent and that sometimes the lesions themselves may entirely disappear. Paretzky¹⁷ recently reported the actual observation of loss of allergy in eighty cases of arrested pulmonary tuberculosis. Neal¹⁸ claimed this to be a sign of arrest under treatment by pneumothorax. In rare instances loss of allergy within a short time after first infection in children has been observed.¹⁹ Though the patient reacts negatively to tuberculin, should reinfection occur his behavior is not that of virgin soil but rather that of a mildly allergic person. This is of importance in assessing the epidemiologic significance of negative reactors and also as an explanation of some of the apparently primary lesions in adults which have recently been reported. That allergy to tuberculin may fade out after mild tuberculous infection was supported by the experimental data of Calmette²⁰ and Guérin. The idea has since been considered by a number of clinical observers (Kristenson,²¹ Troisier and his co-workers,²² Courcoux

and his associates,²³ and Irimescu and Nasta²⁴), who noted that the processes developing on exposure in these persons are unlike either primary or phthisical ones.

A positive reaction to tuberculin represents a state of allergy and indicates a previous tuberculous infection but of course not necessarily the presence of active disease. In fact, in the large majority of reactors the lesions which may still exist are entirely latent and inactive. I have already indicated that this affords a certain degree of protection against reinfection. That the allergic state may be a two-edged sword has also been indicated. The situation has been admirably summarized by Topley²⁵ as follows:

There is a good deal of evidence derived from clinical and radiographical observations to suggest that, though allergy serves as a valuable protective mechanism against reinfection in normal persons with inactive latent foci of tuberculosis, in patients suffering from the disease or in persons with latent active foci, it may have the reverse effect. Such persons, when exposed to reinfection, of either exogenous or endogenous origin, react much more strongly than normal persons. A severe inflammatory disturbance is liable to develop around the active focus, and lead to general toxemia and extension of the local lesion.

If this conception is correct it will be seen that there is no simple relationship existing between allergy and the liability to develop clinical tuberculosis. The relationship is dependent on a number of variable factors, among which the state of the lesions, the general environmental conditions and the risk of exposure to infection are probably three of the most important. If we are to gauge the liability of individual persons to develop clinical tuberculosis, a knowledge of their sensitivity to tuberculin is clearly insufficient. In addition, we shall want to know the number, extent, and degree of activity of all tuberculous foci in the patient's body, together with his general environmental conditions and mode of living. Whether such knowledge, if obtained, would enable us to assess, in terms of probability, the likelihood of tuberculosis developing, we are not in a position to say, but investigations are now on foot which it is hoped will provide an answer to this question—at any rate so far as pulmonary tuberculosis is concerned.

As long ago as 1923 Redeker emphasized that exogenous superinfection tends to exacerbate old foci and bring about dissemination and endogenous metastasization from them. This assumption has since been accepted by a number of workers.²⁶ This is the "exacerbation phthisis" of Ulrici, to which reference has already been made and which is now ascribed to the effect of hypersensitization.

The Intensity of the Reaction.—As to the significance of the intensity of the reaction to tuberculin, although some knowledge exists, it is far from complete. There is reason to believe that the intensity depends largely on the intimacy of contact, involving more frequent exposures to infection as well as larger doses, and also on the time that has elapsed since exposure.

For example, in studies with children Boyd²⁷ found that 48.27 per cent of those in whom the source of infection was found gave a positive reaction to a 1:1,000 dilution and 16.27 per cent a positive reaction to a

1:100 dilution. He said: "The source of infection was found for 60.87 per cent of those children with 3- and 4-plus reactions, and for only 14.28 per cent of those with 1- and 2-plus reactions" and concluded that "the character of the skin reaction is a better index of the intimacy of contact than is the presence of a definite lesion in the x-ray."

From observations on children Schuman²⁸ concluded:

The more recent the exposure the greater is the reaction to tuberculin. It is not definite whether the time-interval dates from the period of the primary infection or from the period of exposure to positive sputum.

The degree of sensitization to tuberculin may be measured either by the intensity of reaction to a standard dose or by the size of the dose required to produce a definite reaction. Recognizing the fact that intimacy of contact may greatly intensify the reaction, Long and his associates²⁹ recommended that under such circumstances the more potent strength of their purified protein derivative be avoided. In this connection it may be stated that this derivative represents a great advance in the preparation of tuberculin and that its general use will tend to extend more accurately our knowledge of the significance of varying reactions.

That hypersensitivity to tuberculin not only may indicate recent or severe exposure but may involve a great risk of the development of "exacerbation phthisis" is indicated by reports such as those of Wilcocks³⁰ in South Africa, who stated:

As regards Tanganyika Territory, it can be stated that in those communities where opportunity for contact is likely to be greatest, we find . . . first, the highest percentage of positive reactors to tuberculin; second, the strongest reactions; and, third, the greatest numbers and proportions of recorded disease. . . . It seems logical, therefore, to think that continuous exposure to exogenous reinfection tends to produce, first, sensitivity, then hypersensitivity, and finally disease.

As exposures to infection as well as individual resistance vary greatly at different times, it is not surprising to find that the sensitivity to tuberculin varies greatly in the same person. The advantage that may be taken of this fact as an indication of the occurrence of a new infection or of the danger of active disease has not been fully explored, but it appears certain that periodic tests with tuberculin are essential to the understanding of the individual case, especially from an epidemiologic point of view, if the full value of surveys with tuberculin is to be realized. For example, it has been shown by Long and Seibert²⁹ in their series of tests with purified protein derivative that the present decline in tuberculosis morbidity is associated with a marked decline in the intensity of allergy; and, on the other hand, it has been shown by Opie and others that morbidity, that is, active phthisis, goes parallel with the incidence of hypersensitiveness, which is a point in favor of those who hold for hypersensitiveness as a reactivating agent.

The degree of allergy varies with the level of tubercularization in the environment, that is, differences in exposure by contact; hence it would appear that it is not the absolute but the relative level which counts. In

persons living in a tuberculized environment, exposed constantly to infection, a permanent high level of allergy is maintained, and the exposure must be greatly intensified to produce a dangerous degree of hypersensitization. On the other hand, in those living in an environment of low tuberculization, tending to exhibit a low level of allergy, a much less intense exposure may produce hypersensitiveness. It would appear, therefore, that it is not the dose of infection alone but the previous degree of allergy which in any individual case indicates the danger of reactivation of lesions through hypersensitiveness. The practical importance of this situation is apparent; i. e., a given amount of exposure to infection may be serious for one person and quite harmless for another.

It must, however, be borne in mind that change in the level of allergy is not the only factor, as has been well emphasized by Topley, who stated:

How much of this activation of latent lesions was due to the allergic condition of the tissues, and how much to the effect of physical fatigue and possibly other environmental conditions in lowering the general resistance of the body, it is impossible to say.

My discussion has served to indicate how complex and at the same time how fascinating is this whole question of allergy in tuberculosis and how much it requires further study.

The present state of knowledge tends to indicate that:

1. Tuberculin allergy is a relative phenomenon, which must always be considered in relation to the level of tuberculization in the environment or the extent of tuberculosis present in the individuals in question.

2. It is not the momentary level of allergy but its relative changes in either direction which are significant.

3. Infection sensitizes. Superinfection hypersensitizes. Hypersensitization may act to promote progression of recent lesions or reactivation of old lesions if it occurs too suddenly or becomes excessive.

SUMMARY AND PRACTICAL APPLICATIONS

1. Continued or frequent exposure to large doses of infection may lead to acute disseminated tuberculosis in previously uninfected persons, especially in young children; or in those already primarily infected it may give rise to active phthisis by the exacerbation of old latent lesions through hypersensitization or possibly by the formation of new pulmonary lesions through exogenous superinfection. Consequently, protection from such undue exposure is of paramount importance in the prevention of tuberculosis. Institutional segregation of patients with advanced infection is by far the most effective step in this direction.

2. Although in most communities from 30 to 80 per cent of the population eventually is infected with tuberculosis, only from 1 to 2 per cent contract active disease. It is therefore as important to analyze why the majority stay well as to discover why the comparatively few become sick. The study of resistance is of as great, if not greater, importance than the study of infection.

3. There is much that is not known about resistance to tuberculosis, and much of our supposed knowledge is based on inference rather than on definite proof. Natural or constitutional resistance would appear to be a real thing, as evidenced by the great variation in susceptibility under similar conditions of infection in individuals, in families and in races. This applies to susceptibility not only to disease but to infection, as shown by an appreciable percentage of exposed children who do not react to tuberculin. It would appear that

this natural resistance can be enhanced through generations, and the question of the possibility of transmission through inheritance of at least a capacity to develop resistance is a live question. More and more is heard of constitutional factors in resistance not only to tuberculosis but to other diseases as well. The development of further knowledge in this direction will merit attention.

4. There is overwhelming evidence that a tuberculous infection successfully met changes the reaction of the body to subsequent infections, whether from within or without, in such a way as to increase resistance. Such acquired resistance is only relative and may be overcome by large doses of infection or may be lowered by various adverse environmental factors. The attainment of this resistance, acquired through many years or even through generations of exposure to repeated small doses of infection, has greatly modified the character of the disease and diminished its prevalence. What the epidemiologic effect will be of the increasing proportion of uninfected persons and their possible exposure to infection later in life from the residual foci of disease in urban centers is one of the great open questions of the future. Opinion is sharply divided as to whether it is better to face the vicissitudes of life with a positive or a negative reaction to tuberculin. If the former, is it better to receive the infection early in childhood or late in adult life? If the latter, what is the danger of contracting an acutely virulent type of tuberculosis rather than a more benign chronic type? On these points also opinions differ.

5. At first sight the two opposing theories of the exogenous and the endogenous pathogenesis of phthisis may seem a technical problem of main interest only to pathologists. When analyzed, however, their practical importance is obvious. If phthisis arises in the main from the inhalation of large or frequent doses of tubercle bacilli and the old residual lesions of previous small infections are innocuous scars, then efforts can be concentrated solely on the prevention of such exposure. If, on the other hand, infections insufficient to cause actual disease leave behind them in the lungs latent foci capable of reactivation not only by exposure to new infection but by numerous environmental factors which, by lowering resistance, allow the bacilli to multiply and the lesions to become active, then these latent lesions assume great importance as the potential sources of phthisis. Many, perhaps the majority, of students now believe that they constitute not only possible but the main factors in the ultimate development of phthisis. The discovery and the management of these potential lesions then become one of the great clinical and public health problems.

6. The discovery of these lesions is accomplished by roentgenograms. They give no physical signs and no symptoms until they become active. The extraordinary extension of roentgenologic surveys is showing them up by the thousands. In the great majority of cases these lesions are latent and innocuous and will always remain so under ordinary conditions of life. It is therefore unnecessary and unjust to submit them to the long treatment indicated for active tuberculosis. They are, however, possible sources of phthisis; consequently the subjects should be kept under regular supervision, with periodic roentgenograms and warnings as to the danger signals of beginning active disease. They should be surrounded by a protective environment, by which is meant freedom from the factors lowering

resistance, on the one hand, and freedom from exposure to hypersensitizing doses of infection, on the other. When activity is discovered early, they respond remarkably well to modern rest treatment, but to detect an early stage requires careful and expert supervision constantly exercised over periods of years. It would appear that the discovery and proper management of latent lesions constitute the greatest opportunity for clinicians to make a real contribution to the prevention of phthisis that exists today. Beginnings only are being made in this direction.

7. Closely associated with the roentgenologic surveys are the survey with tuberculin. They are affording much epidemiologic as well as clinical information of great value. They have been employed largely to determine the extent of infection which exists in a given community at a given time. It would appear that they may have wider possibilities. The reaction to tuberculin in any given person may change; it may become less or entirely disappear, or it may become more marked. To study a community accurately, periodic repetitions of the test would be helpful. These have not yet been done on a wide scale. The results might be expected to give important information as to the real significance of these changes, their possible relationship to the changing incidence of exposure to infection and their possible relationship to the development of clinical disease. A better understanding of the significance of negative reactions would also be a real contribution to our present knowledge, which is now more suggestive than complete.

8. It is possible that as a result of more careful clinical and epidemiologic studies, knowledge might be obtained which would lead to the discrimination between persons who would be a good risk and those who would be a bad risk when unduly exposed to infection. It is obviously impossible, for example, in the matter of medicine and nursing to exclude all young people entering these professions from exposure to tuberculous infection. As a very small percentage of physicians and nurses actually contract the disease even when seriously exposed to infection, it is obvious that other factors than the infection itself are important. The exposure of young people with a negative tuberculin reaction to intimate contact with infection is obviously undesirable. Also, it has been shown that exposure may result in exacerbation of lesions already existing. It would appear at least a possibility that if one could gradually accustom a person whose reaction to tuberculin was negative to small, properly spaced doses of infection, gradual tolerance to larger doses of infection could be achieved. There is certainly evidence that changes of environment that result in sudden increase of allergy may be a factor in the development of clinical disease. By careful study of persons having apparently inactive lesions, a basis of judgment as to who is likely to react unfavorably and who is not might be formed.

On the other hand, it is distinctly a possibility of the future that some form of vaccination may be perfected which will definitely diminish the danger of disease from contact with infection. Experiments with BCG are most interesting and suggestive, but apparently BCG in itself has as yet not been proved to be the ideal vaccine. It is applicable only to the uninfected, and for them its efficacy is not yet proved. The future may provide a form of vaccine to be used by means of repeated small injections over long periods for both infected and uninfected persons.

9. From all these considerations it is obvious that one should carefully consider what is the ultimate goal aimed at for the control of tuberculosis. If it is to be the total eradication of the disease, with an absolutely uninfected community, how seriously should one take the warning of Bushnell and others that eventually such a community of virgin soil might revert to the early epidemiologic stage, in which acute epidemic forms of tuberculosis may appear, due to exposure to the few remaining uneradicated foci? Should one look rather to a form of vaccination, either by control of small doses of infection, such as apparently has been going on throughout the civilized world, on the other hand, to a more accurate and satisfactory form of artificial vaccination?

10. I have touched on only a few of the problems of tuberculosis which are still unsolved. It would appear obvious that the campaign must be based on accurate scientific knowledge and that this is still lacking in some important particulars. Consequently it would be a mistake to assume that the methods now employed are certainly sufficient to solve the tuberculosis problem. They must change in the light of new knowledge, and it may well be that the future holds unwelcome possibilities not visualized by those who consider that the goal would be in sight if the methods which appear adequate according to our present knowledge were thoroughly applied.

ROCHESTER, MINN.

It was shown by Loeb and his associates¹ that adrenalectomized dogs excreted excessive amounts of sodium and chloride and suggested² that the so-called crisis of Addison's disease might result from a similar loss of these electrolytes. It later was demonstrated by one of us (Wilder) with Kendall and others³ that administering potassium to patients with Addison's disease would provoke excretion of sodium and chloride

and precipitate crisis. From this the supposition arose that examination of the urine for sodium and chloride, under standard conditions of administration of potassium, might provide more reliable information about adrenocortical function than frequently is obtained by examination of the blood.

Preliminary studies revealed that the supposition probably was justified. Under conditions imposed, the excretions of chloride and sodium in urine of eight subjects with classic Addison's disease were much greater than those found in a group of eight subjects without evident disease of the adrenal glands. Then a more rigidly standardized procedure, to be described, was adopted, and with it thirty-six additional subjects were examined (table 1). Eight of these were other

the daily intake of potassium ion to 9 Gm. We have never encountered a case of tuberculosis or atrophy of the adrenal glands in which this extended period of salt restriction and high potassium failed to provide clear evidence of cortical insufficiency.

THE STANDARDIZED PROCEDURE

When patients with Addison's disease previously were receiving either adrenal cortex extract or extra salts of sodium, these were withheld on the day preceding the first day of the special examination. Longer periods of such preparation proved to be unnecessary.

On the first day of the examination, and thereafter until its close, a diet low in salt was served, which by calculation provided 0.95 Gm. of chloride ion, 0.59 Gm.

patients with signs and symptoms typical of Addison's disease; six were patients who complained of nondescript asthenias; seven were patients with frank tuberculosis (pulmonary tuberculosis, six cases, three with fever; urogenital tuberculosis, one case); ten were healthy men or women and five were patients with miscellaneous diseases, including chronic infectious arthritis (two cases), metastatic staphylococcal abscess with fever (one case), duodenal ulcer (one case) and nephrosclerosis with hypertension (one case).⁴ Whenever there was any suspicion of involvement of the adrenal glands (patients with unexplained asthenia and those with tuberculosis) additional evidence of adrenocortical adequacy was sought by extending the period of restricted intake of salt, in the standard examination to be described, to a total of six days, for the last three of these enough potassium citrate being given to bring

of sodium and 4.1 Gm. of potassium (table 2). The fluid intake of the first day was not measured, but the free drinking of water was encouraged. On the afternoon of the first day extra potassium was given, as potassium citrate, in a dose representing 33 mg. of potassium per kilogram of body weight (42 mg. of potassium citrate per pound).

On the second day the intake of liquid was made to equal 40 cc. for each kilogram of body weight, and on the morning of this day the dose of potassium citrate was repeated.

On the third day 20 cc. of liquid per kilogram of body weight was given before 11 a. m. At 12 noon of this third day the examination ended, except in those cases in which the period of deprivation of salt was extended in order to obtain additional evidence of the state of adrenocortical function. At the close of every examination, in all cases in which adrenal insufficiency was suspected, an intravenous injection was given of 1,000 cc. of sterile solution containing 50 Gm. of

4. Two other subjects were examined after the compilation of table 1; one a patient with Addison's disease and one with an asthenia thought to be due to carcinomatosis.

d-glucose, 10 Gm. of sodium chloride, 5 Gm. of sodium citrate and 20 cc. of an active preparation of cortical hormone.⁵

Blood was drawn in an oiled syringe from the cubital vein at 8 a. m. of the second day of examination and at 10 a. m. of the third day. It was transferred to cooled 20 cc. hematocrit tubes containing heparin and oil, and the plasma was separated by means of a refrigerated centrifuge. Urine was collected in three periods: from 8 a. m. to 8 p. m. of the second day, from 8 p. m. to 8 a. m. of the third day, and from 8 a. m. to 12 noon of the third day.⁶

RESULTS

A summary of the data obtained by means of this procedure in thirty-five cases is given in table 1.

§ Numbers in parentheses represent milliequivalents.

† Represents blood specimens in middle of four hour period.

Blood Plasma Sodium.—The average value for sodium in the blood of subjects with Addison's disease was distinctly lower than the average for all other subjects. However, the range of values for the former widely overlapped the values found in the other subjects. This was true for the third day of examination as well as for the second day.

5. The constituents of this solution were held ready at all times for immediate use if necessary. One of the patients with Addison's disease developed symptoms of crisis in the afternoon of the second day. In this case, which is omitted from table 1, symptoms typical of the Addisonian crisis were accompanied by an abnormally large excretion of chloride and sodium in the urine. The examination was brought to a close at 8 p. m. on the second day; the solution described was administered and promptly restored the patient to a satisfactory condition.

6. Chloride in plasma was determined by a slight modification of the method of Ancel Keys (The Microdetermination of Chlorides in Biological Materials: Presentation of a Method and an Analysis of Its Use, J. Biol. Chem. 119: 389-403 [July] 1937), that in urine by the Volhard-Harvey titration, with the reagents of J. P. Peters and D. D. Van Slyke (Quantitative Clinical Chemistry: Methods, Baltimore, Williams & Wilkins Company, 1932, vol. 2, pp. 835-836). Sodium in plasma and urine was determined by the method of Butler and Tutthill (quoted by Peters and Van Slyke: Quantitative Clinical Chemistry: Methods, vol. 2, pp. 732-736), and potassium in plasma and urine by the chloroplatinate method of Shohl and Bennett as modified by Eva R. Hartzler (A Note on the Determination of Potassium by the Method of Shohl and Bennett, J. Biol. Chem. 122: 19-20 [Dec.] 1937).

The average depression of these values, from the second to the third day, in subjects with Addison's disease was 19.4 mg. per hundred cubic centimeters; that in subjects without Addison's disease was only 3.6 mg. per hundred cubic centimeters. However, wide overlapping again was evident.

Blood Plasma Chloride.—The statements about the values for sodium in the plasma apply with almost equal force to the values obtained for chloride.

Blood Plasma Potassium.—The average of all values for potassium in the plasma of the subjects with Addison's disease was only slightly higher (about 3 mg. per hundred cubic centimeters) than that of the subjects without Addison's disease. The values for the two groups overlapped widely.

Hematocrit Determinations and Values for Blood Urea.—The hematocrit determinations indicated that the hemoconcentration which occurred during the interval between drawing of the first and second samples of blood was slightly greater in several of the subjects with Addison's disease than in those without Addison's disease. The values for blood urea were elevated in several cases of Addison's disease, so that the mean for this value was abnormal. However, the range of values both for hematocrit determinations and for blood urea extended far into the zone of values found in normal subjects.

Urine Sodium.—The mean value for the excretion of sodium, in terms of milligrams of sodium per kilogram of body weight per hour, in the urine for the twenty-four hours of the second day of examination was more than three times as great for subjects with Addison's disease as for those without; and in the urine of the four hour period of the third day this value was more than five times as great. The individual values for the

two groups showed very little overlapping. There was, however, some of it. On the other hand, when we limited attention to concentration (milligrams per hundred cubic centimeters) of sodium in the urine we found no overlapping of values in the four hour collection of urine of the third day. In this four hour collection the mean for the subjects with Addison's disease was 206.7 mg. per hundred cubic centimeters, with a range of values from 165 to 282, whereas the mean for all controls was only 22.4, with a range from 6 to 85.

Urine Chloride.—The statements relative to excretion and concentration of sodium in the urine apply also to chloride. Of greatest significance was the concentration (milligrams per hundred cubic centimeters) in the urine of the four hour collection of the third day, in which again there was no overlapping of values between the group of subjects with Addison's disease and the controls. In this specimen the mean value for subjects with Addison's disease was 293.4 mg. per hundred cubic centimeters, with a range of from 229 to 356, whereas the mean for all controls was 54.2, with a range from 17 to 141.

This tendency of patients with Addison's disease to excrete urine containing chloride in high concentration becomes even more apparent when it is considered that the concentrations of chloride and sodium in the blood of these patients were usually depressed. The relationship is illustrated in the accompanying chart.

Urine Potassium.—The excretion of potassium was slightly less in the subjects with Addison's disease, but much overlapping occurred between individual values for them and the values obtained for the controls. This

was from 0.36 to 1.51 cc. per minute, that for the controls from 0.52 to 6.2.⁷

COMMENT

On the basis of observations in one case, the suggestion was made by Anderson and Lyall⁸ that the finding of a concentration in the urine of more than 121 mg. per hundred cubic centimeters of chloride ion, when the concentration of plasma chloride is below the minimal normal level of about 320 mg. per hundred

Concentration of chloride in four hour collection of urine, morning of third day of deprivation of sodium chloride. Triangles represent Addison's disease; circles, controls.

cubic centimeters, would strongly suggest the presence of Addison's disease. The objection to their proposal, as we soon found, is that the plasma chloride in Addison's disease frequently is higher than 320 mg. per hundred cubic centimeters. Indeed, in our subjects it sometimes did not fall to that level even under the provocative conditions which we imposed. Our studies also showed that the figure 121 mg. per hundred cubic centimeters for the concentration of chloride ion in the urine is too low for the conditions we imposed. A few of our normal subjects had concentrations higher than this. Our results, however, do bear out the supposition that the excretion of chloride or sodium, under standard conditions of provocation, may serve as an index of the degree of normality of that function of the adrenocortex involved in electrolyte metabolism. The concentration of chloride in the urine on the morning of the third day of a period of deprivation of salt proved to be more significant, diagnostically, than the volume of urine, the concentration of potassium in the urine, the total amount of chloride, sodium or potassium in the urine, or the values or change in values of the chloride, sodium or potassium in the blood.

determination, although proving to be of little significance diagnostically, is of theoretic interest, showing in most cases that the kidneys in Addison's disease retain potassium even when excreting sodium excessively.

Urine Water.—The average volume of the urine in the group of subjects with Addison's disease was significantly smaller than that for the group of controls. The difference was greatest in the four hour period of the third day. Even for this specimen, however, considerable overlapping of individual values was encountered; the range for patients with Addison's disease

7. Marañon, Collazo and Perez (Metabolismo mineral y del agua en la enfermedad de Addison; la prueba del agua, Arch. de med. cir. y. especialid. 38: 344-348 [May 30] 1935), all of whose papers in Spanish have not been available to us, have demonstrated retardation in the excretion of water in Addison's disease. The same has been observed by others in adrenalectomized animals. The patients of Marañon and Collazo, when deprived of food and water for fourteen hours and then given 1,000 cc. of water by mouth, excreted it tardily and in less than normal amount. The disturbance appeared to be proportional to the degree of severity of the disease. Our observations, under conditions more or less comparable, support theirs. However, the volume of urine is less reliable with and those without other support. The latter obviously is less reliable. With less excretion of water, however, in adrenocortical insufficiency an additional factor is to be engaged, so that excretions of chloride (and sodium) are out of proportion to those of water.

8. Anderson, J. A., and Lyall, Alexander: Addison's Disease Due to Suprarenal Atrophy with Previous Thyrotoxicosis and Death from Hypoglycemia, Lancet 1: 1039-1043 (May 1) 1937.

A urinary concentration of chloride in excess of 225 mg. per hundred cubic centimeters, to judge from our observations, is indicative of some abnormality of adrenocortical function, whereas a concentration of less than 125 mg. per hundred cubic centimeters probably can be accepted as evidence of normality. Values for concentration between these two figures are inconclusive and, when obtained in any examination, a longer period of restricted intake of salt may be necessary for diagnosis. However, from our experience such intermediate values will be encountered infrequently.

The presence of complicating organic disease may militate against the diagnostic significance of urinary concentration of chloride. This will apply particularly to uncontrolled diabetes and to some forms of nephritis. It did not apply to the active tuberculosis present in seven of the control subjects in this study (three of them with fever) or to the five patients with other disease (one with fever).⁹

It must be emphasized that the conditions described for the preparation of patients and the conduct of their subsequent examination cannot be neglected, although further investigation may reveal that less rigid regulation will suffice. It also must be emphasized that restriction of sodium chloride and administration of potassium, while involving no apparent risk when the adrenal glands are normal, is a dangerous procedure under conditions of severe adrenal insufficiency. The diagnostic procedure we have instituted calls for relatively small doses of potassium and for a period of deprivation of salt of only fifty-two hours. Thus, it inflicts less risk of collapse than the six day period of restriction imposed by the procedure suggested by Harrop¹⁰ in 1933 and modified by us in 1935.³ Nevertheless, fifty-two hours of restriction of salt, even with small doses of potassium, carries some risk, and the examination of patients by this means must not be undertaken unless bed rest or at least room rest is enforced, continuous nursing attention is provided, and facilities are at hand for immediate intravenous injection in emergency of sodium chloride, sodium citrate and adrenal cortex extract.

OTHER DIAGNOSTIC PROCEDURES

Zwemer and Truskowski¹¹ have proposed the giving of from 10 to 20 mg. of potassium per pound of body weight and at short intervals examining the effect of this on the level of potassium in the blood plasma. Gordon, Sevringhaus and Stark,¹² however, applying the procedure in cases of asthenia, in normal subjects and in cases of Addison's disease, found that "it failed to afford any consistent basis for distinguishing between

these three types of subject." Another objection is the necessity for determining potassium in the blood plasma. This is a difficult and exacting analysis in any laboratory, and few clinicians or hospitals are equipped to do analyses for potassium. A great advantage in the diagnostic test we are proposing is that the only chemical analysis demanded is that of the urine for chloride, requiring a minimum of chemical experience and equipment.

The provocative procedure introduced by Harrop and his associates in 1933, and subsequently modified in the Mayo Clinic to control the intake of potassium, while highly reliable has proved hazardous, as recently was illustrated by a fatal accident reported by Lilienfeld.¹³ The test originally was performed by subjecting the patient to a diet very low in sodium chloride, and the diagnosis was considered positive if symptoms of crisis developed, accompanied by subnormal values for sodium in the blood. The modification used in the Mayo Clinic since 1935 is as follows: On the first three days of the test the suspect is given a diet containing 4 Gm. of potassium, and potassium citrate is added to bring the total intake of potassium ion to 6 Gm. daily. On the next three days the total intake of potassium is raised to 9 Gm.

Injection of insulin, as a diagnostic procedure, has not been helpful. The rationale is the known hypersensitiveness to insulin of patients and animals with adrenocortical insufficiency. However, hypersensitiveness to insulin is not confined to conditions of adrenocortical insufficiency. The same statement applies to administration of epinephrine for diagnostic purposes.

The therapeutic test, based on the response of patients to treatment with injection of adrenal cortex extract, is completely unreliable, as has been emphasized by Kline.¹⁴ One of his patients, with an asthenia previously "benefited" by treatment with adrenal cortex extract, had so little trouble with his adrenal glands that he was able to tolerate a nine day period of rigid restriction of sodium chloride. Later he was subjectively as well off as before, with injections of sterile water. A number of patients who under our observation withstood the six day provocative test supplemented by administration of potassium citrate came to us with a diagnosis of Addison's disease made elsewhere and the story of subjective improvement from treatment with "eschatin" or other adrenal cortex extract. Several of them seemed actually to have been benefited by the low intake of salt and large doses of potassium. To give adrenal cortex extract for long periods, unless indisputable evidence has been obtained of the existence of adrenocortical insufficiency, is wasteful of time, money and valuable material. There also is reason to believe that prolonged treatment with it may be injurious. The injection of adrenal cortex extract into normal rats in large doses quickly produces atrophy of the adrenal cortices.¹⁵

CONCLUSIONS

Under standardized conditions as described, the concentration of either chloride or sodium in the urine of patients with Addison's disease has been diagnostically more significant than any other factor examined, giving more valuable information than the volume of the urine,

9. Winkler and Crankshaw (Chloride Depletion in Conditions Other Than Addison's Disease, *J. Clin. Investigation* **17**:1-7 [Jan.] 1938) have observed large excretions of chloride ion, associated with low values for chloride and sodium in the blood, in three subjects with pulmonary tuberculosis, one subject with carcinoma of the lung and one with arteriosclerotic heart disease. Low values for chloride in the serum were also found in thirteen additional subjects with pulmonary tuberculosis. The authors commented on the importance of this in the differential diagnosis of Addison's disease. The difference in the conditions we imposed makes it impossible to compare the rates of excretion of chloride observed by us with those found by Winkler and Crankshaw. The unreliability of the values for plasma electrolytes as a diagnostic criterion in Addison's disease has been recognized for some time by a number of observers. The finding of high values for nonprotein nitrogen and potassium, and of low values for chloride, sodium and sugar, is suggestive but not diagnostic. The absence of all these abnormalities does not exclude the existence of adrenocortical disease, and low values for chloride and sodium in the plasma, as is shown by our observations and those of Winkler and Crankshaw, occasionally are encountered in other diseases, and even in health.

the concentration of potassium in the urine or the values or change in values during a fifty-two hour period of restricted intake of sodium chloride, of the chloride, sodium or potassium of the blood plasma.

The diagnostic procedure suggested requires fewer days for completion, subjects the patient to less risk of collapse, and in most cases is quite as informative as the six day period of restricted intake of salt heretofore resorted to for diagnostic purposes.

As the concentration of the chloride in the urine gives as important information as that of sodium, the analytic procedure demanded may be limited to analysis for urinary chloride. This represents a distinct advantage, because many clinics and hospitals are not equipped for analytic determinations of sodium or potassium.

Our conclusions are based on examinations of seventeen patients with Addison's disease and thirty-seven controls. The group of controls included ten healthy persons and twenty-seven patients with disease which apparently did not involve the adrenal glands.

FATAL TOXIC REACTIONS ASSOCIATED WITH TRIBROMETHANOL ANESTHESIA

HENRY K. BEECHER, M.D.

BOSTON

Whenever an anesthetic agent has enough good qualities to get it past an early trial period, it seems to take about ten years to evaluate its bad effects. So it is with tribromethanol (avertin) with amylene hydrate. This agent was prepared by Willstätter and Duisberg in 1926.¹ Since that time its sale has been widely promoted by commercial organizations. The term represents a solution of tribromethanol dissolved in amylene hydrate. The latter drug is also an active narcotic. According to Sollmann,² the effects together or separately of these two agents were not studied with the care that should be employed before an agent for general anesthesia is introduced. However, the drug gained a rather widespread popularity, notwithstanding a good many early deaths of patients under it. Enough time has elapsed and enough material is at hand to allow a reasonably accurate estimate to be made of the toxicity of this agent, to allow a consideration of whether its undoubted good qualities outweigh the bad.

The accompanying chart is based on all the cases, 3,934, in which avertin with amylene hydrate was used in the Massachusetts General Hospital³ from the time the first patient was given it, in 1930, until Jan. 1, 1938. The drug quickly increased in use, as the chart shows, and its fall from favor in this hospital was equally rapid. It was never used here in any great proportion of the cases. In 1934, the year in which it was most used, it was administered 734 times. That year a total of 8,069 anesthetics were induced. At the peak of its use, the drug was used in less than 10 per cent of the cases in this hospital.

It may be interesting to consider the factors which have been chiefly responsible for this waxing and

waning of popularity. At this date one's interest lies mainly in a consideration of the circumstances which have contributed to the lessened use of the drug. In order that these limiting influences may be presented in their proper perspective, it will be useful to stop for a moment and consider first the characteristics which led to its popularity.

REASONS FOR THE POPULARITY OF AVERTIN WITH AMYLENE HYDRATE

Probably the outstanding reason for the early success of the drug was that patients like it. Children and nervous adults who have to undergo anesthesia are subjected to a minimum of psychic trauma when this agent is used. Other outstanding reasons for its widespread use are: It is a convenient anesthetic when an operation in or around the airway must be undertaken. It gives quiet breathing and appears to depress the vagal reflexes, which may be very troublesome in intrathoracic operations. Neurosurgeons like it, for if it does not actually lower the intracranial pressure, as has been claimed,⁴ it certainly does not elevate it as much as ether does. According to some authorities, a great advantage is that it allows minimal use of inhalation anesthetics. (This is, to say the least, a questionable advantage when it is gained at the price exacted; see the mortality rate hereafter.) The drug can be used by a novice and allows an inexperienced or inexperienced person to give what appears superficially to be a "good ether." These are the chief reasons for its popularity.

REASONS FOR THE DECLINE IN THE USE OF AVERTIN WITH AMYLENE HYDRATE

1. *Variability of Response.*—The drug had been in use only a little while before it became apparent that patients reacted very differently to a given dose. A good reason for this variability was presented by Sebening.⁵ Twenty patients underwent a rectal injection of a dilute solution of barium sulfate. The volume and the rate of injection were the same as in the case of avertin with amylene hydrate. The following results were observed by roentgen examination: In two cases the entire colon, including the cecum, was filled. The middle of the ascending colon was attained twice and the hepatic flexure four times. The middle of the transverse colon was attained four times and the splenic flexure seven times. In one patient the agent reached only the sigmoid flexure; the following day an injection did not pass the rectosigmoid junction. The causes of such variations are numerous. Important factors are anatomic variations, variations in tone and peristalsis of the bowel and variations in gas and fecal content. The rate of absorption depends largely on the height to which the injected fluid rises. It is an extremely important factor in the toxicity of the drug. A large dose slowly absorbed is not followed by toxic effects; a small dose rapidly absorbed may be. The relatively small difference in size between the usual clinical dose and

With the Approval of the Surgical Executive Committee and from the Surgical Services of the Massachusetts General Hospital.

3. This includes the Baker Memorial Division.

4. J. E. Finesinger and Stanley Cobb (The Cerebral Circulation: XXXIV. The Action of Narcotic Drugs on the Pial Vessels, *J. Pharmacol. & Exper. Therap.* 53: 1 [Jan.] 1935) have found that in cats under anesthesia induced by avertin with amylene hydrate the pial vessels are narrowed and the cerebrospinal fluid pressure falls. This confirms the results of Severs and his associates,² who found that in dogs under this anesthesia the intracranial pressure is greatly lowered. In man they found that the venous pressure is lowered, and they implied that the drug must have a similar effect on the cerebrospinal fluid pressure. As a result of direct observations, however, W. J. Gardner and C. A. Lamb (Effect of "Avertin" on the Cerebrospinal Fluid Pressure, *J. A. M. A.* 96: 2102 [June 30] 1931) stated that a moderate elevation of cerebrospinal fluid pressure is caused in man by this agent.

5. Sebening, Walter: Recent Researches and Clinical Advances in Avertin Narcosis, *Anesth. & Analg.* 11: 145 (July-Aug.) 1932.

the lethal dose accentuates the importance of this variability in the rate of absorption.

2. *Rectal Irritation.*—With proper testing of the anesthetic solution immediately prior to its injection, rectal irritation should be trivial. I have seen one patient have transient diarrhea even though the solution had been tested with congo red immediately before use and was not decomposed. Occasionally other rectal irritations are reported.

3. *Prolonged Induction Period When an Inhalation Anesthetic Is Used as a Supplement.*—The induction period may be a hazardous time for the patient. The respiratory depression frequently experienced by patients under avertin with amylene hydrate results in a slow intake of the volatile anesthetic, for, as Haggard⁶ has shown so well, the rate of induction of anesthesia (with a given concentration of inhalation anesthetic) depends directly on the volume per minute of air breathed. To be sure, this delay is of no great moment in many cases; but in those patients who have much sputum or an abnormal quantity of mucus, the delay in establishing a proper airway may be serious. Formerly, in this hospital in patients about to undergo lobectomy for bronchiectasis a basal anesthesia was induced by avertin with amylene hydrate. Before inhalation anesthesia adequate to allow the insertion of an intratracheal tube for bronchial aspiration had been obtained, the patient in some cases had passed through a dangerous condition of anoxia because of the partial obstruction of the airway from the purulent bronchial secretions.

4. *Alarming Immediate Depression.*—This is usually transient, lasting from ten to thirty minutes. By the time the patient emerges from the anesthetizing room and comes into the surgeon's presence, he has as a rule partially if not completely recovered. It is impossible to say how much his ultimate recovery has been delayed by the initial period of low blood pressure and anoxia. One can be reasonably certain that this depression, even if transient, has reduced the patient's ability to withstand the tax of a major operation. It seems probable that if more surgeons saw such episodes they would be less keen in their enthusiasm for the agent. Unfortunately the depression is seen chiefly by the anesthetist, who may not report it or who, unhappily, may not even be aware of it if the anesthetization is carried out in a darkened room, as is frequently the case. The outstanding features of the depression are concerned chiefly with the respiration and the circulation.

The Respiration: The drug has a profoundly depressant effect on the respiratory center. This depression is greater than that occasioned by chloroform. Not only is the respiration slowed; it becomes shallow as well. The oxygenating power of the body is reduced. Anoxia and cyanosis result.

The Circulation: The force of the heart beat is weakened and the rate slowed. The fall in blood pressure which occurs is due to two main effects: direct cardiac depression and depression of the vasomotor center (Parsons,⁷ Seevers and his co-workers,⁸ Nowak,⁹

Cushny¹⁰ and Sollmann.² In case 6, reported hereafter, death may have been produced by ventricular fibrillation.

5. *Delayed Effects.*—Occasionally the effects described are prolonged or delayed. Not infrequently the patient is irrational or unconscious a long time. There is then danger that he will injure himself or acquire hypostatic pneumonia. There is the need for continuous, constant and intelligent nursing; it is not always available. In addition to the prolonged depression of the central nervous system, the kidneys and liver may suffer severe organic damage (cases 2 and 7).

6. *Numerous Contraindications.*—It has been learned, at the cost of a good many lives, that there are many contraindications to the use of avertin with amylene hydrate, notably hepatic and renal disease (these will be considered in "Comment"), heart disease, myxedema, conditions in which the oxygenating ability of the body is impaired (e. g., when the vital capacity is reduced or anemia is present), widespread sepsis, cachexia, inflam-

The rise and decline in the use of avertin with amylene hydrate at the Massachusetts General Hospital.

mation, infection or ulceration of the intestine from any cause and old age.

7. *Impossibility of Efficiently Removing the Agent Once Toxic Effects Become Evident.*—This drawback is of course common to all the non-volatile anesthetics.

8. *The Fatalities.*—Soon after the drug was introduced there were a good many deaths of patients under it. The doses recommended were too large. After the early fatalities and the shift to the smaller doses now used, a body of arbitrary statements gradually developed. It is commonly said that children are never damaged by a dose of 100 mg. per kilogram of body weight and, further, that the anesthetic can safely be given to adults if the 80 mg. dose is not exceeded, provided the liver and the kidneys are normal. That these are dangerous statements is illustrated by the cases to be reported.

THE DEATHS

Of the eight chief causes for the decline in the popularity of avertin with amylene hydrate, the most important is the last one, the fatalities.

There are many difficulties in the way of evaluating deaths due to this anesthetic. There are always the complicating factors of the patient's disease and of his operation; and in many cases, though not in all, the drug has been supplemented by nitrous oxide, ether or both. If deaths occur when it has been supplemented by another anesthetic agent, it is necessary to rely on a series large enough to indicate whether or not the death rate is significantly increased when avertin with amylene hydrate is used; that is, whether it is increased above the rate for the supplementing agent.

The cases to be listed were chosen from a considerable number. A case was included only if death could not be attributed to any other cause; even then it was chosen only if toxic reactions occurred which appeared to be directly attributable to the avertin with amylene hydrate. The fact that the choice of this anesthetic was due to bad judgment in a given case was not taken as a valid reason for excluding that case. In the light of present knowledge, the choice appears to have been based on poor judgment in several of the cases.

This anesthetic has been widely used in the Massachusetts General Hospital as the anesthetic for intracranial operations, and a number of the patients have died under circumstances in which it has not been possible to distinguish between the effect of the anesthetic and of the patient's disease. The cases, 268, of tumor of the brain in which this anesthetic was used have accordingly been excluded from consideration.

These limitations in the choice of cases tend to give a conservative picture; even so, the serious toxic reactions were surprisingly frequent and the death rate unreasonably high.

One can have little patience with statements based on memory or on a series of cases published without an intensive search for and record of suspicious cases. Many of the surgeons in this hospital would have said that no deaths due to this agent had occurred here. Others are convinced that not all cases properly belonging in this list have been included. The aim has been to call attention to the variety of toxic reactions to the drug and to indicate as accurately and fairly as possible the order of the death rate due to this agent.

REPORT OF CASES

CASE 1.—History.—A white woman aged 81, a widow, entered this hospital first on May 12, 1931. Her history was typical of chronic cholecystitis. The edge of the liver was palpable 2 fingerbreadths below the costal margin, and the epigastric region was very tender. The only abnormalities were a coarse systolic murmur heard all over the precordium, a blood pressure of 190/120 and a positive reaction to the Graham test. The reasonable observation was made by the intern who examined the patient that she was a poor risk for ether anesthesia and that spinal anesthesia and avertin with amylene hydrate were contraindicated. For this reason and because of her age, the patient was discharged without operation, since she was not uncomfortable at the time.

Two and one-half months later, July 27, the patient was readmitted because of nausea and colicky pains in the right upper quadrant. At this time her blood pressure was 165/78 and her physical condition was otherwise unchanged. Operation was decided on.

July 30 the patient received subcutaneous preanesthetic injection of $\frac{1}{2}$ grain (0.02 Gm.) of pantopon (the hydrochlorides of the alkaloids of opium, principally morphine) and $\frac{1}{150}$ grain (0.0004 Gm.) of atropine. With considerable boldness the surgeon decided to use 100 mg. of avertin with amylene hydrate per kilogram of body weight rectally. He supplemented it

with 50 cc. of 1 per cent procaine hydrochloride injected into the abdominal wall and light ether anesthesia induced by the drop method.

At the start of the anesthesia the blood pressure was 180/85. Ten minutes after the avertin had been administered the blood pressure had fallen to 120/60. The operation was delayed for forty minutes after the rectal injection had been made. Twenty minutes after it was started the blood pressure had fallen to one third of its initial value, that is, to 60/30. The anesthesia appears to have been chiefly responsible for this drop, for, notwithstanding the continuance of the operation, the blood pressure rose steadily from the low point, which occurred twenty minutes after the start of the operation, to 150/80 at the end. Presumably this rise coincided with partial detoxification of the avertin. A cholecystectomy with drainage was carried out.

The patient never regained consciousness. Two hours after the operation was completed the blood pressure began to fall. The record contains the note that the patient "gradually became more cyanotic." When the cyanosis began is not stated. Coarse tracheal rales developed eight and one-half hours after the avertin was given, and the patient died twenty-one and one-half hours after its administration.

Necropsy.—The smaller bronchi were filled with a bloody, frothy fluid. The lungs showed slight congestion and moderate edema in the upper lobes, with more marked congestion in both lower lobes. One or two small areas were present in the right lower lobe which suggested patches of early bronchopneumonia.

The heart was markedly contracted. Considerable arteriosclerosis was present in the cerebral, coronary and general arterial systems.

The arteries of the kidneys showed marked fibrous intimal thickening. An occasional glomerulus was completely hyalinized, with atrophy of some of the associated tubules and dilatation of others.

The cells of the liver showed a diffuse fine vacuolization.

The Brain: There was complete absence of cells in a considerable portion of the alveus of the cornu ammonis. The cytoarchitecture elsewhere was fairly well preserved. In the cerebral cortex, in the various parts examined, no Nissl granules were to be seen in the cell bodies of the processes, but the cells were filled with a fine, dustlike material, which gave them a homogeneous appearance and brought out the process more distinctly than is the case with normal cells when only Nissl granules are stained. The nuclei were pale, fairly round, possibly enlarged and usually central. Many of the nucleoli occupied an eccentric or even a peripheral position in the nuclei. Satellite cells were not increased in number. Some of the Purkinje cells of the cerebellum were small and pale. Their number appeared to be diminished. So far as the appearance of the ganglion cells was concerned, the possibility of an artefact had to be kept in mind, but the changes may have been caused by a toxic substance.

Anatomic Diagnoses: The diagnoses were arteriosclerosis, general, cerebral and coronary; bronchopneumonia, early; chronic vascular nephritis, benign type.

This was a case of early use of the drug, and today the patient would not be given avertin with amylene hydrate, for it was plainly contraindicated by her age, by her hepatic disease and by her hypertension.

The facts incriminating this drug are: The profound fall in blood pressure was obviously due to the anesthetic, since it occurred before the operation began and since, in spite of the operation, the blood pressure rose steadily and rapidly throughout the last hour to a reasonable level for the patient, 150/80; the patient failed to recover consciousness, even though the circulation remained in good condition for many hours after the anesthetic was given; at necropsy toxic damage to the brain was suggested. The impaired kidneys, it is now known, greatly increased the hazard. The

absence of any other adequate explanation derived from the necropsy points to the drug as the probable chief cause of death.

CASE 2.—History.—A white married woman, aged 36, a housewife, entered the hospital July 24, 1931, complaining of pain and "numbness" in the perineum and of urinary incontinence of three months' duration. She had no control of the anal sphincter. A bowel movement never occurred without an enema. Physical examination showed a well developed and obese young woman. The lungs and the cardiovascular system were normal. At entry the blood pressure was 146/100; three days later it was 130/60. The patient had a roughly saddle-like distribution of anesthesia. At entry a voided specimen of urine contained thick mucus, numerous red cells and a large trace of albumin, perhaps from the blood.

July 27, after preliminary subcutaneous medication with $\frac{1}{4}$ grain (0.01 Gm.) of morphine and $\frac{1}{150}$ grain (0.0004 Gm.) of atropine, the patient was given rectally a 90 mg. per kilogram of body weight dose of avertin with amylene hydrate. It was supplemented with ether. In the following hour the systolic blood pressure gradually fell from 130 to 88. The patient underwent laminectomy from the fourth lumbar to the first sacral vertebra, inclusive, and excision of a chondroma, which had compressed the roots of the cauda equina. Her condition at the end of the operation was considered to be "fairly good." In the two and one-half hours following the operation the patient's blood pressure declined further, to 75/45, and then gradually rose. During this period the pulse rate fluctuated between 100 and 130. She recovered from the operation, and a month after the operation, August 27, was discharged as "relieved."

About seven weeks later, October 15, the patient reentered the hospital, complaining of a severe pain in the back for the preceding month. She said that the numbness previously described had gradually cleared to a considerable extent. She still had no control of the bladder or of the anal sphincter. She suffered from marked constipation. The physical examination gave about the same results as at her previous entry. A hypesthetic area, sharply confined to the lower lumbar segments, was found. A specimen of urine obtained by catheter showed the "slightest possible trace" of albumin, rare red cells and numerous white cells. In seven determinations the specific gravity varied from 1.010 to 1.030.

A new block of the spinal canal was suspected, and a cisternal puncture with injection of iodized poppyseed oil was carried out November 9. She was having so much pain that use of a general anesthetic was necessary. As preanesthetic medication, $\frac{1}{4}$ grain of morphine and $\frac{1}{150}$ grain of atropine were used. An 80 mg. per kilogram of body weight dose of avertin with amylene hydrate was administered rectally. It was supplemented with the open administration of ether. But few significant data were recorded on the anesthesia chart. According to these the patient did not experience any untoward reaction. This procedure gave evidence of a block in the region of the third dorsal vertebra. Roentgenograms were taken with the patient under ether anesthesia November 13.

December 4 the patient underwent a third anesthesia, induced by an 80 mg. per kilogram of body weight dose of avertin with amylene hydrate. This was preceded by subcutaneous injection of $\frac{1}{4}$ grain of morphine at 9 a. m. and again at 10:15 a. m. With the second injection of morphine, $\frac{1}{150}$ grain of atropine was given. The avertin was administered rectally at 10:30 a. m. It was supplemented by nitrous oxide with oxygen and ether.

At the time the avertin was given, the blood pressure was 130/88 and the pulse rate 105. There was a steady, rapid fall in blood pressure, and forty minutes later, that is, five minutes after the operation was started, the blood pressure could not be taken and the pulse rate had risen to 158. For thirty minutes the blood pressure could not be determined. After injection of ephedrine one reading of 120/90 was made. In ten minutes the pressure had fallen to 95/80, where it remained until the operation was finished. The operation required one hour and twenty-five minutes. Laminectomy was carried out. A block of the spinal canal could not be found. The region of the

spinothalamic tracts was incised. The patient was conscious when returned to her bed. She received a blood transfusion of 500 cc.

The patient appeared to make a satisfactory immediate convalescence from the anesthesia, except that there was practically no formation of urine. Four days after the operation determinations of the nonprotein nitrogen revealed a marked elevation, the content being from 66 to 83 mg. per hundred cubic centimeters. In the two days following, the content rose to 120 mg. The content of blood chlorides was reported as 561 mg. December 8 the icteric index was 20 and the red cell count 2,830,000; the hemoglobin content was from 55 to 60 per cent. The white cell count was 19,500 with 97 per cent polymorphonuclears. December 9 the serum protein content was reported as 4.5 mg. per hundred cubic centimeters.

Notwithstanding the use of diuretics, the patient formed scarcely any urine after her last operation. Uremic convulsions developed and she died eight and one-half days after the third administration of avertin with amylene hydrate in four and one-half months.

Necropsy.—Examination of the head was not made. Ecchymotic spots were scattered all over the skin. The wound was clean.

Lungs: The trachea and bronchi contained a moderate amount of frothy fluid. The lungs were markedly edematous. A large amount of frothy fluid could be expressed from the cut surface of the upper lobes. The cut surfaces of the lower lobes appeared congested, purplish red and of a doughy consistency.

Kidneys: They were enlarged and weighed 575 Gm. The capsular space of the glomeruli was wider than usual and filled with debris from inspissated urine. The capsule was not thickened. Many of the cells remaining in the tufts were necrotic. There were large collections of lymphocytes mixed with a few polymorphonuclears throughout the stroma. A few of the glomeruli were completely hyalinized. A limited and relatively symmetric portion of all the tubules, apparently in the Henle loops, showed swelling, pyknosis of the nuclei and desquamation.

Anatomic Diagnoses: The diagnoses were chondroma of the spinal cord, recurrent; acute nephrosis; bronchopneumonia, slight; edema of the lungs; cholelithiasis; hydronephrosis, slight.

After the patient's death it was learned that she had had convulsions at the time of pregnancy. During her stay in the hospital she had some infection of the urinary tract. With such a history, this patient would not be given avertin with amylene hydrate today.

It is impossible to say how much damage to the kidneys the patient had before the first anesthesia, as the preoperative sample of urine, containing red blood cells, was a voided specimen. From a consideration of the size of the kidneys and the microscopic picture it appears to have been slight. The renal shutdown, the acute nephrosis and the pulmonary edema appear to have been consequences of the anesthesia.

CASE 3.—A white married housewife, aged 56, entered the hospital Jan. 12, 1932, complaining of intermittent asthma of one year's duration, which had followed a "cold." She had had daily attacks for the preceding five months and required epinephrine four or five times daily. Physical examination showed that the heart was slightly enlarged to the left. An apical systolic murmur was present; the sounds were of fair quality; the blood pressure was 140/90. The peripheral vessels were definitely sclerosed. Examination of the lungs showed musical rales and prolonged expiration as the only abnormalities. Two specimens of urine contained the "slightest possible trace" of albumin; the sediment was not remarkable. A blood count showed 15 per cent eosinophils, 12,800 white cells, 5,280,000 red cells and 75 per cent hemoglobin. The nonprotein nitrogen content was 29 mg. per hundred cubic centimeters. The Hinton test was negative. The temperature was normal, and the pulse rate varied from 90 to 110. Roentgen examination revealed the presence of gallstones. January 22 the patient's heart and

lungs were reexamined and found to be "in good shape." That day she underwent operation, for, after considerable study, it appeared probable that an infected gallbladder was responsible for her asthma.

Peanesthetic medication of $\frac{1}{6}$ grain of morphine and $\frac{1}{150}$ grain of atropine was given subcutaneously. A 90 mg. per kilogram of body weight dose of avertin with amylene hydrate was administered rectally at 10:30 a. m., and ten minutes later the operation was started. The avertin was supplemented with "a little" nitrous oxide with oxygen. The operation, which consisted of a cholecystectomy with the removal of two gallstones, required only thirty-five minutes. The surgeon's record contains the note that "everything went well." The patient's respiration, pulse, blood pressure and color were normal throughout the operation. A half hour after the operation the blood pressure had fallen to 90/55, where it remained for some hours. By the following morning it had risen to 110/70.

About eight hours after the anesthetic was administered the patient was still considered to be in good condition, though she had not recovered consciousness.

The day after operation the unconscious patient was having "considerable typical asthma." The temperature had risen abruptly to 102 F. (rectally). Apparently she was considered to be in a satisfactory state except for the failure to recover consciousness. Twenty-four hours after the operation she began to be very cyanotic. This cyanosis was most marked in the extremities, especially the hands. It was relieved at once by use of an oxygen tent but returned promptly whenever the patient was placed in room air.

The next day, that is, two days after the operation, the respiratory rate rose sharply from normal to 35, and it climbed steadily to 48 in the succeeding twelve hours. During this time the pulse rate had risen to 160 and the temperature to 103.3 F. (rectally). On this day, forty-eight hours after operation, though no dulness could be detected, the chest was full of "bubbling, watery rales" (? pulmonary edema). The patient died sixty-four hours after administration of the anesthetic without regaining consciousness.

Postmortem examination was not allowed. The patient failed to recover consciousness, and it must be concluded that for some reason she was unable to detoxify the avertin with amylene hydrate though she appeared to be in good condition except for the unconsciousness for twenty-four hours. Pulmonary edema developed. Cyanosis, with peripheral stasis of blood, is a common finding when the circulation is impaired by toxic agents.

CASE 4.—History.—A white Canadian widow, aged 65, entered the hospital Jan. 15, 1932, complaining that she had had weakness and tarry stools for two weeks. Physical examination showed a pale, fairly well developed and moderately well nourished woman with normal lungs and a normal cardiovascular system. The blood pressure was 126/70. Abdominal examination revealed a hard, slightly tender mass in the epigastrium. The number of red cells varied from 1,650,000 to 2,100,000 and the hemoglobin content from 40 to 45 per cent. On smear the red cells appeared typical of secondary anemia. The urine showed from the "slightest possible trace" to a "very slight trace" of albumin; the sediment was not remarkable. The stools were bloody. The patient was given two transfusions before operation and two afterward.

January 22, after preanesthetic medication with $\frac{1}{6}$ grain of morphine and $\frac{1}{150}$ grain of atropine, 80 mg. per kilogram of body weight of avertin with amylene hydrate was given rectally. This was supplemented by nitrous oxide-oxygen and ether anesthesia. A partial gastric resection was carried out, and a leiomyosarcoma excised. A Billroth II anastomosis was made. In the ten minutes following rectal administration of the drug the blood pressure fell from 120/75 to 95/60, and it gradually subsided, so that after one hour it was 83/53. It then rose, so that by the end of a second hour, at which time the operation was completed, it was 95/60. The pulse rate twenty minutes after the avertin was administered had risen

from 90 to 120. The respirations were shallow and slow, the rate being about 15 during much of the first hour; the rate rose to from 20 to 25 during the last hour of operation. The patient was considered to be in fairly good condition by the time the operation was completed.

The record for January 24 contains the rather ambiguous statement "Patient's immediate recovery from the operation two days ago was excellent, *but she has not been conscious.*" (The italics are mine.) Coarse tracheal rales were heard, and she was placed in an oxygen tent. Cyanosis was not observed. While it can appear when the blood contains only 30 per cent hemoglobin, it might easily have been overlooked with the degree of anemia present in this patient. The rectal temperature in the postoperative days fluctuated from 101 to 104 F., and the pulse rate remained around 120. The afternoon of the second day following operation the blood pressure began to fall, and the patient died sixty-one hours after the anesthetic was administered, without regaining consciousness.

Necropsy.—There was no evidence of peritonitis. The right pleural cavity contained 200 cc. of clear, colorless fluid. The right lung was "markedly edematous" and slightly congested. The left lung was "markedly edematous" and congested.

Kidneys: There were hyalinization of some of the glomeruli and considerable intimal thickening of the larger vessels.

Liver: Numerous macroscopic yellowish brown areas were scattered throughout the parenchyma. Microscopic examination showed slight central congestion.

Brain: No lesion of the brain was observed which might explain the clinical picture.

Anatomic Diagnoses: The diagnoses were sarcoma of the stomach; slight bronchopneumonia in the lower lobe of the right lung; edema and congestion of the lungs; hydrothorax, slight, on the right side; cholelithiasis, ampulla of Vater; arteriosclerosis; chronic vascular nephritis.

There were edema and congestion of the lungs and chronic vascular nephritis. One can only speculate as to whether the nephritis significantly retarded the elimination of the avertin with amylene hydrate. Probably it did. There is a question also whether the marked anemia, in conjunction with the depressant effects of the avertin and the nitrous oxide used, did not produce cerebral damage due to anoxemia. Whatever the mechanism, it appears likely that the avertin was an important factor in this patient's death.

Several factors would now contraindicate the use of avertin with amylene hydrate in this case: the patient's age, her anemia and the possible damage to the kidneys (albuminuria).

CASE 5.—A white woman aged 64 entered the hospital April 10, 1933, complaining of intermittent pain in the right side of the face, which had lasted for nine years. The pain was brought on by eating, by cold air and by touching or washing the face. All three divisions of the fifth nerve were involved. Physical examination showed a well developed woman with normal heart and lungs. The blood pressure was 130/80. No abnormalities were discerned except that she was poorly nourished. The urine was normal except for occasional red blood cells in a voided specimen; the Wassermann reaction of the spinal fluid was negative; a roentgenogram of the skull showed nothing abnormal. The patient was sent home, where she was to remain until the malnourishment could be overcome. She returned in one month, May 11. At this time she was still rather poorly nourished. The urine showed a specific gravity of from 1.012 to 1.016. Two voided specimens contained "the slightest possible trace" of albumin. A few hyaline casts and red blood cells were found. One specimen contained granular casts. The red cell count was 4,200,000 and the hemoglobin content was 70 per cent.

On the morning of May 12 the patient was given a 70 mg. per kilogram of body weight dose of avertin with amylene hydrate. This was not supplemented either by preoperative medication or by other anesthetic agents. It was administered rectally. At the beginning of the anesthesia the patient's blood

pressure was 130/70; the pulse rate was 82. After the rectal injection the operation was delayed thirty-eight minutes. During this period the blood pressure fell steadily from its initial value of 130/70 to 70/40. The operation was started and at this time the blood pressure rose rapidly to 140/90, where it remained during most of the operation. The operation consisted of section of the posterior root of the right fifth nerve. This required fifty-nine minutes. By the time it was completed the blood pressure had fallen to 110/75 and the pulse rate had risen to 120.

The operation was described by the surgeon as "an easy one." There was practically no bleeding. To quote from the record: "Patient seemed in very good condition after the operation. She apparently recovered from the anesthetic (according to the nurse's notes the patient was conscious three hours after the operation was completed), though she was drowsy and confused. Then she became more comatose; the blood pressure fell steadily. Her condition became steadily worse until she died." Unfortunately many of the details of the postoperative period were not recorded. The temperature rose gradually for two days, to 104 F. (rectally), and the pulse rate rose to 125 before the respiratory rate had exceeded 24. In the twelve hours immediately preceding death the respiratory rate rather rapidly rose from 24 to 40. Death occurred sixty-four hours after the anesthetic was administered.

Clinically the death could not be explained. Those attending the patient considered it to be due to the anesthetic. Autopsy was not allowed.

The delayed rise in the respiratory rate, as well as the failure to detect pneumonia clinically, does not suggest that pneumonia was the explanation of this death. Clinically, sepsis was not found to be responsible. The patient's failure to recover from her drowsy and confused state immediately after the operation was not explained unless the anesthetic was responsible.

The patient's age and the probable impairment of her kidneys would today make the use of avertin with amylene hydrate undesirable.

CASE 6.—A Polish girl aged 12 entered the hospital June 15, 1935, with a diagnosis of arthritis deformans (Still's disease) of five years' duration. She complained of inability to walk because of the changes in her ankles and had been confined to bed for a year and a half. Physical examination showed a well nourished girl with marked deformities of the hands and feet. The cardiovascular system was normal; the blood pressure, 120/80. The urine was normal except for one specimen, which showed "a slight trace" of albumin; however, this was a voided specimen. The red cell count was 4,980,000; the hemoglobin content, 70 per cent. The differential count was normal. The white cell count was 11,300 on admission and a week later was 15,900. The stools were normal. The nonprotein nitrogen content was 20 mg. per hundred cubic centimeters. The Hinton test was negative. The temperature was normal.

July 12 the patient was given a subcutaneous injection of $\frac{1}{12}$ grain (0.005 Gm.) of morphine and an 80 mg. per kilogram of body weight dose of avertin with amylene hydrate, administered rectally. Nitrous oxide with oxygen was used to supplement this drug. While the patient was under anesthesia both hands and wrists were manipulated. No significant changes occurred in pulse rate, respiratory rate, blood pressure or color. The surgeon's note states that "the patient stood the procedure well and left the operating room in good condition." She regained consciousness two and one-half hours after the avertin was administered. For three days after this manipulation her temperature rose to 100 F.; it was then normal for three and one-half days.

July 19 the patient was given a subcutaneous injection of $\frac{1}{16}$ grain (0.004 Gm.) of morphine. This was followed in thirty-five minutes by a rectal injection of 80 mg. per kilogram of body weight of avertin with amylene hydrate. Before anesthesia the blood pressure was recorded as 90/58 and the pulse rate as 108. Ten minutes later these readings were essentially unchanged. Fifteen minutes after the avertin was administered it was supplemented with nitrous oxide and oxygen.

Both ankles were manipulated. Suddenly, twenty minutes after the rectal injection had been given, the respirations became shallow and the patient cyanotic. The anesthetist was unable to determine the blood pressure, and the pulse could not be palpated or the heart sounds heard. Artificial respiration was started, oxygen under positive pressure being used. The patient took three or four convulsive inspirations and then stopped. There was no response to stimulants and the patient died. Autopsy was not allowed.

Though it cannot be proved, this case suggests that ventricular fibrillation was the cause of death (see "Comment").

CASE 7.—History.—A white single girl aged 19 entered the hospital July 6, 1937, complaining of recurrent substernal pain of over two years' duration. This nonradiating pain appeared most often during meals and occasionally woke the patient up at night. She vomited with the pain on two occasions but not in the year before entry. Examination showed a well developed, well nourished, healthy looking young girl who appeared normal. The blood pressure was 104/60. The urine and the blood count were normal. A Hinton test was negative. The temperature was normal and the pulse rate 80.

July 19, after preanesthetic medication with $\frac{1}{100}$ grain (0.0006 Gm.) of atropine administered subcutaneously, the patient was given 80 mg. per kilogram of body weight of avertin with amylene hydrate rectally. At this time her blood pressure was 120/70, her pulse rate 100 and her respiratory rate 20. In eight minutes she was asleep. Ten minutes after the anesthetic had been given the blood pressure could not be taken. The respirations were slow and shallow. A few minutes later the pulse rate was 140. The respirations became regular and normal twenty minutes after the drug was administered. The blood pressure was 120/60 and the pulse rate 168 twenty minutes later. The pulse rate rapidly declined to 130. The avertin was supplemented with nitrous oxide and oxygen for a few minutes, and then ether and oxygen were administered. Because of the marked depression at the onset, the operation was delayed and did not get under way until one hour after the avertin had been given. The operation required two hours and twenty minutes. It consisted of uneventful removal of a neurofibroma of the mediastinum. No shock was present. The blood pressure persisted at about 135/85; the pulse was rather rapid, the rate fluctuating around 140 (from 130 to 155). The respiratory rate during operation was 40. Throughout the operation there was no sustained tendency of the pulse rate to rise or of the blood pressure to fall. Very little bleeding was encountered. When the patient was returned to her bed at noon she appeared to be in good condition.

An hour after the completion of the operation the blood pressure was still normal, 120/60, and the pulse rate was 132. During the ensuing afternoon and evening there was some fluctuation of the blood pressure, but for more than fifteen hours after the operation the systolic pressure never fell below 95. (At entry the systolic pressure was 104.)

About seven hours after the avertin was administered, the special nurse in charge of the case thought the patient was about to regain consciousness, for she stirred and seemed to be not deeply asleep. Eight hours after the drug was given she became restless, and the nurse gave her $\frac{1}{2}$ grain (0.02 Gm.) of pantopon subcutaneously. This quieted her but did not have any other appreciable effect. At 10:30 p. m., some thirteen hours after the avertin was administered, she again became restless, and the nurse repeated the administration of pantopon. This time the patient's respirations became depressed and considerable cyanosis appeared. She appeared to recover gradually from this condition. She again became restless about five hours later, at 4 a. m., and the pantopon was given a third time. The patient's respirations then became very depressed and gasping. Marked cyanosis appeared, the pulse became weak and the blood pressure fell to 55/35. In about half an hour the pulse improved in character but became irregular; the cyanosis lessened. There was no evidence of cardiac tamponade. The blood pressure remained low. At 7 a. m. the day following operation the rectal temperature was 102 F. By 11 a. m. it had risen abruptly to 106.7 F.

Coramine injected intravenously improved the patient's respirations temporarily. Three transfusions of 500 cc. of blood were given without avail over a twenty-four hour period after the operation.

From eighteen hours after administration of the anesthetic until the patient's death thirty-four and one-half hours after the drug was given, she presented the appearance of a person responding to an overwhelming toxic agent. The blood pressure was low, the skin hot and dry and peripheral stasis of the blood marked. The skin was very cyanotic. Pressure areas remained blanched for some seconds. The clinical diagnosis at that time was streptococcal infection of the mediastinum. Material from the region was cultured after the patient's death but no infection found.

Necropsy.—The head and extremities were not examined. The right lung showed "very diminished aeration" and was "markedly congested" throughout. The left lung showed a moderate number of purplish, atelectatic lobular areas and was engorged. No evidence of consolidation was found. Microscopically, all the blood vessels and the alveolar capillaries were seen to be markedly congested. Most of the alveoli in the section were slightly atelectatic. The alveolar spaces contained an eosinophilic serous deposit, some monocytes (a few of which contain phagocytized brown pigment), a moderate number of red cells and some polymorphonuclear neutrophils. In one area the neutrophils were densely collected but without appreciable fibrin. Some of the bronchioles contained clumps of neutrophils.

Liver: Grossly, a few areas of yellowish mottling were seen on section throughout the parenchyma. Microscopically, the central and to some extent the midzonal portions of the lobules stood out sharply from the rest of the parenchyma. The hepatic cells were more eosinophilic, were vacuolated and for the most part were separated from one another so that they appeared to be floating as individual round cells. In a few places fibrin and a few neutrophils could be seen. The sinusoidal endothelium was well separated from the hepatic cells, and in some of the central areas there had been diapedesis of the red cells through it.

Kidneys: The convoluted tubules showed some cloudy swelling.

Rectum: In the ampulla a number of tiny, reddened, slightly vascular areas about 1 mm. in diameter were seen in the mucosa; these gave a somewhat peppered appearance. Microscopically, the most superficial layer of the epithelium was seen to have desquamated. One small area exhibited hemorrhage.

Anatomic Diagnoses: The diagnoses were pulmonary congestion and atelectasis, bilateral; congestion of the spleen; central necrosis of the liver, early.

For eighteen hours after the administration of the avertin with amylene hydrate the patient appeared to be in a satisfactory condition except for her failure to regain consciousness. The drug appears to have been responsible.

COMMENT

There is always, perhaps, a temptation to draw too many and too broad conclusions from material of this kind. It will be useful, however, to consider the common features of these cases.

Six of the seven patients who died¹¹ showed an immediate depression after avertin with amylene hydrate was given. In the seventh the depression did not appear until the end of a short operation. Cyanosis was frequently recorded. Only one patient of seven recovered full consciousness; one other was at best drowsy and confused; five did not recover consciousness. Pulmonary edema was a terminal feature in half the cases.

11. Curiously, all the patients who died were women, yet there were a few more men than women in the series. An analysis of 500 of the cases spread out over the entire list suggests that the types of operation were comparable for the two sexes. Statistically this appears significant; however, it seems probable that some other explanation is the correct one. It will be interesting to check the point in other series.

In three cases (2, 6 and 7) the condition appears strikingly reminiscent of damage due to chloroform, and, one is compelled to add, it is reminiscent also of fatal anoxia.

The suspicion that tribromethanol and chloroform produce similar toxic effects is not new. Tribromethanol, the chief anesthetic agent in avertin with amylene hydrate, bears the same relationship to ethyl alcohol as chloroform bears to methane. In the case of both methane and ethyl alcohol the anesthetic action has been greatly intensified by the substitution of three halogen atoms for three hydrogen atoms. It is possible that many of the toxic effects of chloroform can be attributed to hydrochloric acid, which may be formed when chloroform is destroyed. It is not unreasonable to suppose that when tribromethanol is broken down hydrobromic acid may be formed and produce effects somewhat similar to those produced by hydrochloric acid. Traces of bromine have been found in the breath and the sweat after the administration of avertin (Parsons¹²). The drug is generally believed to be detoxified in the liver by conjugation with glycuronic acid and then excreted as a complex organic compound of bromine.

It has been assumed that the chloroform-like toxic effects are produced only by large doses. That this is not the case is shown by the data presented here. While much dwelling on the chloroform analogy is not justified by the evidence at hand, there are clinical as well as theoretic data to suggest that the observed similarities in effect are more than chance.

Chloroform notoriously produces death by acute damage in three regions of the body: ventricular fibrillation in the heart, tubular damage in the kidneys, and central necrosis in the liver.

Death from ventricular fibrillation has never been proved in a human subject who died under chloroform anesthesia; yet ever since Goodman Levy¹³ showed, in his classic studies of death from ventricular fibrillation in animals under chloroform anesthesia, that the clinical observations in man and in animals are so similar, it has been assumed that the patient who dies under light chloroform anesthesia dies of ventricular fibrillation. In case 6 the circumstances preceding and during death, especially the sudden cardiac standstill apparently before the respiration failed, strongly suggest that ventricular fibrillation was the cause of death.

In case 2 the anesthetic produced tubular damage to the kidneys like that caused by chloroform. In case 7, in which there was early central necrosis in the liver, the damage in this region was like that due to chloroform.

Attention should be drawn to the fact that the great majority of the cases reported here describe the use of avertin with amylene hydrate in adults. Children appear to tolerate the drug better than adults. However, the death in the 12 year old patient reported here is a reminder that children are not immune to the toxic effects of the drug.

It is useless to consider mortality figures for a given anesthetic in any but the most general terms. The data usually presented describe not the total death rate, which may not permit accurate evaluation, but rather how often the circulation fails and sudden death occurs. (For example, the role of the anesthetic in causing

12. Parsons, F. B.: Avertin, *Canad. M. A. J.* 24: 59 (Jan.) 1931.

13. Levy, A. G.: Sudden Death Under Light Chloroform Anesthesia, *Proc. Physiol. Soc., J. Physiol.* 42: iii (Jan.) 1911; *Chloroform Anesthesia*, London, John Bale, Sons and Danielsson, Ltd., 1922.

death from postoperative pulmonary complications has never been satisfactorily demonstrated.) So it is with the data presented in this paper. The deaths attributed to avertin with amylene hydrate and included here have been chosen conservatively.

Means chosen from numerous statistical studies suggest that comparative data on mortality would appear approximately as shown in the accompanying table.

It is probable that any agent which produces fatalities with the frequency of avertin with amylene hydrate must injure a great many patients whose injuries go undetected or are attributed to the patient's disease.

The ratio of one death in 500 cases cannot be considered in any precise mathematical sense. A series many times larger than the 3,666 cases considered here would be necessary to give the ratio anything like a literal value.

If four of the cases included here were eliminated from consideration because today the contraindications would be recognized and the drug not administered, the death rate would be in the ratio of one death to 1,200 cases.

Comparative Death Rates

Nitrous oxide.....	1: 50,000 (including short cases)
Ether	1: 5,000
Cyclopropane	1: 3,500
Chloroform	1: 2,000
Spinal anesthesia.....	1: 1,500
Avertin with amylene hydrate	1: 500 (7 deaths in 3,666 * cases)
	or
	1: 1,200†

* Excluding cases of tumor of the brain.

† Excluding four cases in which this anesthetic would be plainly contraindicated today.

The point remains: avertin with amylene hydrate makes a poor showing even when compared with a toxic agent like chloroform. It appears to be more dangerous than the discredited chloroform.

SUMMARY

In eight years avertin with amylene hydrate was used at the Massachusetts General Hospital in 3,934 cases. Though the use of the drug has waxed and waned in this period, it was never used in more than 10 per cent of the cases in which anesthesia was employed. Eight factors have been chiefly responsible for the lessened use of the drug. Seven deaths were associated with its use. According to the mortality rate, considered in its relation to the death rate for other common anesthetic agents, avertin with amylene hydrate appears to be more toxic than chloroform.

The Thalamus and Emotion.—The supposed evidence that the thalamus adds the affective or emotional character to sensations breaks down completely when subjected to critical analysis. The affective changes resulting from thalamic lesions are restricted to a small group of somesthetic sensations and cannot be interpreted as a general change in affectivity. The changes correlate definitely with the special properties of conduction, summation, and irradiation of this group of sensory processes and not at all with a specific locus in the thalamus. The pathological changes following thalamic lesions are primarily in the character of sensations, in intensity, duration, localization, and are therefore not relevant to the problem of affect. There is no evidence whatever that the thalamus contributes facilitative impulses which might form a basis for the motivational aspects of emotion.—Lashley, K. S.: *The Thalamus and Emotion, Psychol. Rev.* 45:42 (Jan.) 1938.

CONCENTRATED HUMAN BLOOD SERUM AS A DIURETIC IN THE TREAT- MENT OF NEPHROSIS

PRELIMINARY REPORT

C. A. ALDRICH, M.D.

WINNETKA, ILL.

JOSEPH STOKES JR., M.D.

PHILADELPHIA

W. PRICE KILLINGSWORTH, M.D.

CHICAGO

AND

AIMS C. MCGUINNESS, M.D.

PHILADELPHIA

The treatment of nephrosis has been especially interesting to clinicians because in this disease edema is usually found without complicating cardiac or arterial lesions. Comparatively recently it has been realized that in nephrosis the kidney need not be severely or irreparably damaged and that, even in the stage of greatest disturbance in water excretion, tests for renal function may give approximately normal results. Such observations have stimulated search for therapeutic agents acting elsewhere than on the kidneys in patients with this condition.

Thus, on the hypothesis that nephrosis might be due to a metabolic disturbance involving the thyroid gland, thyroxine and thyroid extract have been used, with results which at times have appeared promising. Likewise, because it was conceived that a sort of "diabetes albuminuricus" might explain the phenomena of nephrosis, high protein diets were tried, with enough success to warrant their use in most clinics. The theory has been stressed that the water balance between the blood vessels and the tissues is disturbed because of the prolonged loss of plasma protein through the kidneys. However, not one of the many explanations offered has been entirely satisfactory in accounting for all the clinical manifestations or in establishing the exact pathogenesis of nephrosis.

A phenomenon of great interest to clinicians at the present time is the loss of serum albumin in nephrosis. While all the plasma protein fractions are reduced, the most marked loss occurs in the albumin fraction, and this results in a reversal of the albumin-globulin ratio. Since the albumin molecule is much smaller than that of the globulin and therefore more important in the maintenance of colloid osmotic pressure, this marked reduction in the albumin fraction reduces the pressure of the blood plasma to a considerable extent, thus theoretically accounting for an escape of water into the tissues.

Although the foregoing explanation appears logical, critical studies of the blood serum made just before and just after diuresis have shown no measurable increase in the albumin. It seems probable, therefore, that this change in plasma proteins is but one of several factors responsible for the edema.

Dr. Killingsworth is fellow of the Otho S. A. Sprague Memorial Institute.

Aided by a grant from the lyophile serum fund of the Abington Memorial Hospital.

From the nephritic services of the Children's Memorial Hospital of Chicago and the Children's Hospital of Philadelphia.

Dr. Joseph Calvin and Dr. H. H. Boyle allowed us to treat their patients, and Dr. Gladys Dick and Dr. Sidney O. Levinson of the Samuel Deutsch Serum Center gave us technical assistance in preparing portions of the serum.

Because of the loss of serum albumin and of its possible significance in reducing the water excretion, many substances have been injected into the blood stream in an attempt to increase its power to hold water and to remove it from the tissues. Among these have been hypertonic solution of dextrose and of sucrose, solution of acacia, whole blood, and hypertonic salt solution. Although some help has been obtained from these agents, not one of them has proved uniformly and continuously successful.

In the case of whole blood, the amount it is possible to inject is limited by the fact that, as a rule, before sufficient protein can be given an excess of red blood cells is provided. However, it has been noted that a relatively small transfusion often seems to initiate a sizable diuresis.

During the past few years our attention has been called to the possibility of treatment with blood serum

and a commercial solvent. Serum processed by this method becomes a dry, porous powder which may be redissolved in one fourth or less of its original volume of water or serum. When large amounts of serum were to be stored for intravenous use, it was necessary to obtain pools of serum from many adults. This serum was then processed in pools, redissolved, filtered for the removal of fat globules and again processed, after which it was safe for intravenous use in fourfold concentration.²

From the earliest development of this method it was obvious that such concentrated serum had many possible uses. Among these uses, the restoration of serum protein values and the raising of the oncotic pressure of the blood serum for its dehydrating effect on localized or generalized collections of extracellular fluid were perhaps the most obvious. In order to test the therapeutic possibilities of such concentrated serum, two

types of patients were selected at the Children's Hospital of Philadelphia: infants with hydrocephalus (reported elsewhere³) and children with lipid nephrosis and edema.

Our observations provided us with a logical reason to attempt the administration of larger or more concentrated doses of serum, after which consultation between the Philadelphia and the Chicago authors took place and resulted in this combined study.

REPORT OF CASES

The following case reports refer strictly to patients with nephrosis. We were able to treat one patient with mild and eight patients with advanced nephrotic edema. In none of the hundreds of urinalyses made for these patients were enough red blood cells found to produce a posi-

tive benzidine test on the centrifuged sediment, as such an observation in our clinics would rule out the diagnosis of nephrosis. Tests of renal function except for excretion of water were approximately normal in all but case 6. There was evidence that secondary renal damage was occurring in the kidneys of this patient after many years of illness. All the patients except the first presented marked anasarca. All presented marked albuminuria and cylindruria not associated with elevation of the systemic blood pressure. Clinical observations are therefore omitted from the case reports.

CASE 1.—A. C., a girl aged 6 years, was admitted to the Children's Hospital of Philadelphia Jan. 8, 1937, with slight edema of the eyes and the ankles. She had typical nephrosis,

2. Mudd, Stuart; Florsdorf, E. W.; Eagle, Harry; Stokes, Joseph, Jr., and McGuinness, Aims C.: The Preservation and Concentration of Human Serum for Clinical Use, *J. A. M. A.* 107:956-959 (Sept. 19) 1936.

3. Several infants with hydrocephalus were treated with marked reduction of intracranial tension lasting many weeks (Hughes, Joseph; Mudd, Stuart, and Strecker, E. A.: Treatment of Increased Intracranial Pressure by Concentrated Human Lyophile Serum, *Tr. Am. Neurol. A.* 62: 118-125, 1936).

Fig. 1 (case 2).—Complete diuresis, with loss of 32 pounds (60 per cent of normal weight) in two weeks. Two small injections were given. The patient completely recovered, and the urine was normal.

alone. During this time large doses, 100 cc., of convalescent scarlet fever serum were given intravenously at the Children's Memorial Hospital to nephrotic patients who had pneumococcic peritonitis as a complication (to be reported elsewhere). It was frequently observed that, in addition to an immediate drop in temperature, spectacular diuresis was obtained. The explanation for this result was not obvious. It was felt that it might be an immune reaction, an antitoxic effect or possibly a replacement in the blood of some deficient factor.

With the development of the lyophile process by Florsdorf and Mudd¹ in 1934, a method was made available not only for the preservation of serums and other biologic materials but for the concentration of such products. The lyophile process consists essentially in the vacuum dehydration of material previously frozen at a low temperature in a bath of carbon dioxide ice

1. Florsdorf, E. W., and Mudd, Stuart: Procedure and Apparatus for Preserving in "Lyophile" Form of Serum and Other Biological Substances, *J. Immunol.* 29: 389-425 (Nov.) 1935.

which had been treated for four years by different methods. During this time she had undergone repeated attacks of major edema.

On January 15 she was given 25 cc. of three times concentrated human serum intravenously. In four days she lost all the edema, 2 pounds (907 Gm.). She then began to gain in weight, and on January 23 she was given 125 cc. of whole

followed. The albuminuria slowly decreased, and on August 2 urinalysis gave negative results. At the time of writing the patient is clinically well (fig. 2).

CASE 4.—A. M., a Negro girl aged 4 years, was admitted to the Cook County Hospital on June 24, 1937, with nephrosis. Through Dr. Joseph Calvin, we were permitted to treat her with 80 cc. of four times concentrated serum intravenously on June 28. Prompt and complete diuresis followed, with a loss of 7 pounds (3.2 Kg.) in weight. Within one month the urine became normal, and it has remained so.

CASE 5.—G. B., a boy aged 11 years, was admitted to the Children's Memorial Hospital July 14, 1937, with nephrosis. He had been under observation since February 27, both in the hospital and in the dispensary. In addition to the nephrosis, he had definite hypothyroidism. It had been found that the administration of from 2 to 3 grains (0.12 to 0.18 Gm.) of thyroid extract daily would control his tendency toward edema. One week before admission the thyroid medication was discontinued, with the result that he gained 7 pounds (3.2 Kg.) in weight in edema fluid. On the day of entrance he was given 65 cc. of four times concentrated serum intravenously and no other treatment. In the next seven days he lost all this accumulated fluid in complete diuresis. He was then kept edema free by means of 3 grains of thyroid extract administered daily (fig. 3).

CASE 6.—F. M., a Negro girl aged 5 years, with nephrosis, who had been observed most of the time since 1935 in the Children's Memorial Hospital, had recently shown signs of secondary renal sclerosis, marked reduction in renal function, fixation of the specific gravity in the low range, retention of

Fig. 2 (case 3).—Complete diuresis, with loss of 7½ pounds (23 per cent of normal weight), following transfusion of 250 cc. of blood and one injection of lyophilic serum. The patient made a complete recovery, with normal urine, in one month and is clinically well at the time of writing.

blood serum, with no perceptible change in her weight. Two days later 35 cc. of four times concentrated serum was administered, after which she again lost all her edema. She remained edema free until discharge from the hospital, but her subsequent course is not known. No change in serum proteins was noted.

CASE 2.—M. Y., a girl aged 8 years, was admitted to the Children's Memorial Hospital on April 13, 1937, with the usual symptoms of nephrosis. This was her first attack. There was a continuous gain in weight for forty-two days, her weight increasing from 64 pounds to 82 pounds (29 to 37 Kg.), and various treatments were tried ineffectually.

On May 23, 65 cc. of four times concentrated human serum was given intravenously. After a slight loss in weight (fig. 1), the weight again rose, and accordingly the dose was repeated on May 25. Complete diuresis, with the loss of 32 pounds (14.5 Kg.), followed. The patient was discharged in good condition except for albuminuria on June 16.

She remained symptom free for six weeks and then had a less severe attack of edema, resulting in spontaneous diuresis. After this attack the albumin gradually disappeared and she remained clinically well.

CASE 3.—C. P., a boy aged 7 years, had the typical picture of nephrosis May 1, 1937. After three weeks' observation at home, he entered the Evanston Hospital on May 22. On this day a transfusion of 250 cc. of whole blood was given. The weight fell somewhat but again increased, and on May 27 he was given 50 cc. of four times concentrated serum intravenously. Prompt complete diuresis, with the loss of 8 pounds (3.6 Kg.),

Fig. 3 (case 5).—Complete diuresis, with loss of 7 pounds (10 per cent of normal weight), following one injection of lyophilic serum. The fluid eliminated had accumulated through interruption of thyroid medication; the patient was definitely hypothyroid in type.

nitrogenous substances, increased blood pressure and an unusual disturbance in her mineral metabolism, with a reduction of the blood. On July 3 and 8 she was given injection of 65 cc. She also had glycosuria without hyperglycemia.

While edematous, though still in a stable state of water balance, she was given on June 22, 1937, a transfusion of whole blood. On July 3 and 8 she was given injections of 65 cc.

of four times concentrated serum intravenously. No perceptible effect was noted on the weight or the urinary output. At the time of writing she is unimproved and is being observed in a convalescent home (fig. 4).

CASE 7.—J. F., a white boy aged 6 years, with nephrosis, had been observed in the Children's Memorial Hospital for a period subsequent to July 11, 1934. On July 7, 1937, he was readmitted with an infected throat and generalized edema. On July 7, 9, 15 and 28 he received 65 cc. of four times concentrated serum intravenously. The chart shows a possible delayed response, but since edema persisted we cannot be sure of any beneficial result. No more serum was available. The patient afterward died of septicemia with pneumococcic peritonitis. Autopsy showed the typical appearances of lipoid nephrosis in addition to those of the terminal infection.

CASE 8.—N. T., a boy aged 3 years, was admitted to the Children's Memorial Hospital with nephrosis of one month's duration. On July 26, 1937, he was given 65 cc. of four

mately 30 per cent of her normal weight, in edema fluid. All symptoms of nephrosis have since disappeared and the urine is normal.

TECHNIC OF ADMINISTRATION

The lyophile serum is distributed in sterile bottles marked as to the number of cubic centimeters of serum from which the dried powder was derived. It had previously been found that this powder could be dissolved in one fourth its original volume of distilled water. This was the concentration used in our first cases. Later it was found that the same amount of compatible blood serum would dissolve the powder, so that a concentration of five times could be used. This made a thick, honey-like, syrupy solution, which could be injected directly with little difficulty by means of what we designate in our hospitals as a "scalp transfusion" set (fig. 5) or with a simple 30 or 50 cc. Luer syringe. The size of the needle used depended on the caliber of the patient's vein, a 20 or a 22 gage needle usually being satisfactory. Occasionally, owing to the massive edema present, it was necessary to cut down on either the great saphenous vein at the ankle or on one of the veins in the cubital fossa. However, the superficial jugular vein may be used safely.

The concentrated serum was injected slowly, not more than 5 cc. a minute. When a reaction occurred with the first dose of serum, all subsequent injections contained from 3 to 5 minims of solution of 1:1,000 epinephrine hydrochloride. It is necessary to state here that care must be exercised to prevent this concentrated serum from escaping into the tissues, as it is quite painful, causing rapid and intense local swelling at a site at which it is spilled. The serum when accidentally injected into the tissues caused no necrosis or slough. Venous thrombosis did not follow the injections.

Because there are often large fat globules in the lyophile serum, it is safer to pass it through a coarse filter (Berkefeld N) to prevent the possibility of fat embolism. All serum should be freshly prepared with distilled water or compatible serum and used immediately.

It was felt that until the proper dose was determined by experience it would be safer to use frequent small injections. Accordingly, we did not in this series exceed 80 cc., or the equivalent of about 320 cc. of normal serum. It was noted that even this small amount apparently induced diuresis in some of the patients.

Reactions to the serum were usually mild and febrile and lasted for only a few hours, although in two cases sharp reactions accompanied by chills and high fever were seen.

Fig. 4 (case 6).—No response to therapy. The patient had secondarily damaged kidneys, with glycosuria and impaired mineral metabolism.

times concentrated serum intravenously. Two days later the symptoms of peritonitis developed, and erysipeloid cutaneous lesions appeared on the thighs and the abdomen. On July 30, 100 cc. of convalescent scarlet fever serum was injected with 65 cc. of concentrated blood serum. The pain and fever subsided, but no diuresis occurred. The administration of concentrated serum was repeated on August 5, in the same dose, with no benefit. An abdominal paracentesis gave some relief on August 11.

This patient finally died in another attack with sepsis.

CASE 9.—G. P., a girl aged 3 years, was admitted to the Children's Memorial Hospital on Feb. 7, 1938, with a typical history and symptoms of nephrosis, which began the first week of January. During the succeeding two months she gained approximately 15 pounds (6.8 Kg.) in spite of various efforts to reduce her edema. Two days after admission she was given a transfusion of 150 cc. of whole blood, after which her weight increased $3\frac{1}{2}$ pounds (1.5 Kg.). On February 25 she was given 30 cc. of four times concentrated lyophile serum, and a second injection of 20 cc. of the same material was given on February 26. Diuresis, which resulted in a loss of 10 pounds (4.5 Kg.), began after the first injection. She was discharged edema free on March 2, 1938, having lost 10 pounds, approxi-

COMMENT

Critical study of the use of this method seems to indicate that some diuretic effect results from the intravenous injection of human lyophile serum as we used it. It is equally obvious that the method used is not completely satisfactory, as the treatment failed in three of our nine cases. These failures may be dependent on the severity of the condition, inadequate dosage or an unknown complicating factor.

Serum Protein Values Taken Before and After Administration of Lyophile Serum

Case No.	Amount of Serum Used, Cc.	Total Proteins *		Albumin		Globulin	
		Before	After	Before	After	Before	After
2	130	3.3	3.79	1.4	1.7	1.9	2.09
3	50	3.67	4.27	1.86	1.66	1.81	2.61
4	80	5.35	6.1	2.72	4.0	2.63	2.1
5	65	3.5	4.7	1.6	1.7	1.9	3.0
6	130	4.2	4.4	2.1	2.0	2.1	2.4
7	195	3.6	2.9	1.7	1.2	1.9	1.7
8	315	2.8	3.4	1.1	1.2	1.7	2.2

* The serum protein values are in milligrams per hundred cubic centimeters, calculated in the regular chemical manner (not refractometric). The figures here listed are for already concentrated serum, each cubic centimeter of concentrated serum representing from 4 to 5 cc. of original liquid serum.

We fully realize that spontaneous diuresis occurs frequently with nephrosis and that some of our apparently good results might have been due to a coincidental renal crisis. On the other hand, it can hardly have been fortuitous that in six of the first nine cases serum had been injected on the day before the diuresis began. Furthermore, the results in case 5 can hardly be explained on the basis of chance occurrence. The patient, who had been kept at a stationary weight for several weeks by thyroid extract, was allowed to become edematous by the withdrawal of the medication. While he was still increasing in weight at the rate of 1 pound (453 Gm.) daily, serum was administered. This medication was immediately followed by the occurrence of complete diuresis.

It is difficult to conclude that the effects noted were due to a strictly quantitative osmotic action of the serum. If such were the case, one would hardly expect the diuretic effect to go on for many days, until the edema was completely eliminated, without replenishment with more concentrated serum protein. It is suggested, therefore, that in addition to its osmotic action the serum when favorable results are seen supplies some substance or substances which set off the patient's own mechanism of diuresis.

The accompanying table, showing the blood protein values before and two days after injections, is given to demonstrate that the diuresis could not have been due to the mere replacement of serum proteins. It will be noted that the increase, particularly in the albumin fraction, was never of sufficient degree to be significant.

The fact that four of the patients made a complete recovery, including the secretion of normal urine, supports the idea that the treatment may have initiated some unknown physiologic response. Similar recoveries have been observed by many clinicians after spontaneous renal crises. In fact, the urine may become permanently normal within two days of the beginning of such a process.

The delayed and incomplete response shown in case 7 suggests that if more serum had been available the result might have been more striking.

In the two patients who showed no perceptible response, there were complicating factors worth noting. Patient 6 had severely damaged kidneys, as shown by the very poor results of function tests. In addition, the sugar and the mineral metabolism, factors of considerable importance in maintaining the water balance of the body, were severely disturbed. Patient 8 was dangerously ill with fatal pneumococcal peritonitis and septicemia.

The mere intravenous injection of a "water hungry" protein may explain in part the favorable responses, but it is probable that other factors are present which must be considered and investigated. More serum will be available in the future, with which a more exhaustive study from the clinical and the chemical standpoint will be made.

SUMMARY AND CONCLUSIONS

In six of nine patients with typical lipid nephrosis who were treated during the edematous phases with concentrated (lyophile) human blood serum, complete and immediate diuresis took place. Delayed and incomplete diuresis occurred in one patient. In two patients

Fig. 5.—Scalp transfusion set.

no beneficial results were noted. Four patients not only lost their edema but had normal urine within a few weeks of treatment and have been clinically well to the time of writing.

These encouraging but conflicting results suggest the need for further investigation as to the physiologic mechanism involved and as to the optimum dose.

The patients with a favorable response lost weight in a way similar to that in which weight is lost in a spontaneous renal crisis; this suggests that the process is initiated in some way by the treatment.

FACTORS IN NEONATAL DEATHS

CHICAGO

Although there has been a definite reduction in mortality throughout the United States for infants under 1 year of age during the last twenty years, but little reduction has occurred in mortality for infants under 2 weeks of age. A further reduction in neonatal mortality will depend on a determination of the factors responsible for the deaths.

METHOD OF INVESTIGATION

Our investigation of the deaths of infants¹ showed that a large majority of death certificates in Chicago did not contain the true cause of death. The true cause in many cases was not known and could not be established without a satisfactory necropsy. During 1936 a campaign was undertaken to increase the number of satisfactory necropsies on infants.

TABLE 1.—Five Major Causes of Death in Infants
During 1936 and 1937

	Pre-mature	Full Term	Total	Per Cent Total Autopsies
I. Intracranial hemorrhage.....	130	107	237	22.7
II. Congenital malformations ²	62	101	163	15.6
III. Pneumonia.....	46	38	84	8.1
IV. Asphyxia.....	42	23	65	6.2
V. Undetermined—that is, without demonstrable pathologic lesions other than atelectasis.....	320	42	362	

By carefully studying the anatomic diagnoses, clinical records and laboratory results, accurate data concerning causes of infant deaths were obtained. Cerebral hemorrhage, congenital malformations, pneumonia and asphyxia were found among the leading causes of death. Many neonatal deaths occurred in premature infants without demonstrable pathologic lesions other than atelectasis. These causes did not appear with corresponding frequency on the death certificates when necropsies were not performed.

During 1936 and 1937 there were 3,725 deaths in infants under 1 year of age. Satisfactory necropsies were performed on 1,642.^{3a} The causes of death as determined by these satisfactory necropsies and by careful investigation of the clinical records and laboratory results are used mainly as the basis of this study. The five major causes of death during these two years are given in table 1.

An apparent increase in deaths from certain conditions is explained by the greater percentage of satisfactory necropsies obtained during 1937.

Nearly all the deaths to which complications of pregnancy or labor contribute occur within the first two weeks of life and usually within the first few days.

If an infant dies after living one month or more, it is generally safe to assume that the death is not the result of antenatal or intranatal complications. Therefore, in studying the effect of antenatal and intranatal factors on neonatal mortality, we have used the group of full term infants who died between the ages of 1 and 11 months inclusive² as a basis of comparison with all infants (both premature and full term) who died during the first two weeks of life.³ The 146 deaths of premature infants which occurred between the ages of 1 and 11 months inclusive, out of the 3,725 total deaths, were so few that they are not included in the analysis; their inclusion would have made but slight changes in the figures and greatly complicated the presentation.

The small group of infants who died in the age period from 2 weeks to 1 month, as well as the prematurely born infants who died after one month, is considered by us as on the borderline; that is, there is less certainty as to whether antenatal and intranatal complications were a factor in their deaths. Therefore, the group in the age period from 2 weeks to 1 month is not considered in the comparison.

In the analysis all the 2,283 infants (both premature and full term) who died in the first two weeks are compared with the 1,109 full term infants who died between the ages of 1 and 11 months inclusive. In the case of infants who died in the first two weeks, a detailed study is made of the factors possibly responsible for death. This is done first by determining the number of and comparing the incidence of factors associated with pregnancy and labor for (a) mothers whose infants died from particular causes, such as intracranial hemorrhage, as shown by satisfactory necropsies, and (b) mothers whose infants died from all causes.

It is done secondly by determining the number of and comparing the incidence of factors associated with pregnancy and labor for (a) mothers whose prematurely born infants died and (b) mothers whose full term infants died.⁴

These comparisons have been made to determine if possible (a) factors that are particularly important in contributing to all neonatal deaths (of both full term and premature infants); (b) factors that are particularly important in contributing to neonatal deaths of premature infants; (c) factors that are particularly important in contributing to neonatal deaths of full term infants, and (d) factors that are particularly important in contributing to neonatal deaths of both premature and full term infants from such specific causes as intracranial hemorrhage, pneumonia and asphyxia, and in cases in which there was no demonstrable pathologic lesion.

The ten antenatal or intranatal factors discussed are those which experience has indicated might have an important bearing on neonatal deaths. These factors are (1) the complications of pregnancy, of labor or of both; (2) operative procedures; (3) the use of solution of posterior pituitary; (4) the use of analgesics; (5) dry labor; (6) breech presentation; (7) multiple births; (8) antepartum care; (9) parity, and (10) syphilis. The incidence of these factors is shown in table 2.

2. In this group are included the infants who were 30 or more days and less than 1 year of age at the time of death.

3. This group was used because the necessary information was available for comparison and could not be secured in reference to living infants. The group was considered a survivors of the obstetric hazards and is sufficiently large to be representative of the living infants.

4. The differences in percentages were considered significant only in those instances in which they were at least three times the standard error. In many cases the differences were from four to twelve times the standard error.

1. Bundesen, H. N.; Fishbein, W. I.; Dahms, O. A., and Potter, Edith L.: Factors Responsible for Failure Further to Reduce Infant Mortality, J. A. M. A. 109: 337-343 (July 31) 1937.

3a. Satisfactory necropsies were performed in 35 per cent of the infants who died during 1936, in 53 per cent during 1937, and in 83.5 per cent up to June 21, 1938.

In a discussion of the causes of deaths in the neonatal period, stillbirths should be included; an analysis of stillbirths will be presented in a subsequent paper.

1. TOTAL COMPLICATIONS OF PREGNANCY, OF LABOR OR OF BOTH

In the group comprising 1,048 infants, 468 mothers had complications of pregnancy, 467 had complications of labor and 113 had complications of pregnancy and labor combined.

Complications of pregnancy, of labor or of both occurred in the mothers of 45.8 per cent of the 2,283⁵ infants who died under the age of 2 weeks, 46.3 per cent of the 1,401 premature infants who died under 2 weeks, 45.2 per cent of the 882 full term infants who died under 2 weeks and 17.4 per cent of the 1,109 full term infants who died between the ages of 1 and 11 months inclusive during 1936 and 1937.

The frequency of maternal complications in the deaths from intracranial hemorrhage (56.6 per cent), pneumonia (58.4 per cent) and asphyxia (60 per cent) in the neonatal period is greater than the frequency of such complications in deaths from all causes in the neonatal period (45.8 per cent). This would indicate that complications of pregnancy and labor are particularly important in neonatal deaths from intracranial hemorrhage, pneumonia and asphyxia. Although complications seem to occur less frequently when the infant dies without any demonstrable pathologic lesion (42 per cent), the difference is within the range of chance.

(a) *Complications of Pregnancy.*⁷—Complications of pregnancy occurred in the mothers of 20.5 per cent of the 2,283 infants who died under the age of 2 weeks, 26.5 per cent of the 1,401 premature infants who died under 2 weeks, 10.9 per cent of the 882 full term infants

* Percentages given are those of the cases in which the data were available.

The difference between 45.8 per cent and 17.4 per cent is significant; it indicates that complications of pregnancy, of labor or of both are important factors in the deaths of infants under 2 weeks.

Such complications did not occur any more often in mothers of premature infants who died neonatally (46.3 per cent) than in mothers of full term infants who died neonatally (45.2 per cent).

During 1936 and 1937 there were 237 neonatal deaths from intracranial hemorrhage, eighty-four from pneumonia, sixty-five from asphyxia and 362 without any demonstrable pathologic lesion.

Complications of pregnancy, of labor or of both occurred in the mothers of (a) 56.6 per cent of the 237 infants who died under 2 weeks⁶ from intracranial hemorrhage, (b) 58.4 per cent of the eighty-four infants who died under 2 weeks from pneumonia, (c) 60 per cent of the sixty-five infants who died under 2 weeks from asphyxia, and (d) 42 per cent of the 362 infants who died under 2 weeks without demonstrable pathologic lesions.

who died under 2 weeks and 8.1 per cent of the 1,109 full term infants who died between 1 and 11 months inclusive.

The proportion of complications of pregnancy in the mothers of both premature and full term infants who died under 2 weeks is more than twice as great as in the mothers of the infants who died between 1 and 11 months inclusive. Thus, the proportion of the complications of pregnancy in the mothers of premature infants (26.5 per cent) who died under 2 weeks is more than twice as great as in the mothers of full term infants (10.9 per cent) who died in the same period. These figures indicate that the complications of pregnancy are important in deaths during the first two weeks, particularly in deaths of premature infants.

Complications of pregnancy occurred in the mothers of (a) 18.6 per cent of the 237 infants who died from intracranial hemorrhage, (b) 31 per cent of the eighty-four infants who died from pneumonia, (c) 12.3 per cent of the sixty-five infants who died from asphyxia and (d) 24.3 per cent of the 362 infants who died in which demonstrable pathologic lesions were absent.

The frequency of complications of pregnancy is about as great for all deaths during the neonatal period (20.5

7. By this we refer only to complications occurring before the onset of labor.

5. This group is made up of 1,401 premature infants and of 882 full term infants.

6. In the following pages the discussion of deaths from intracranial hemorrhage, pneumonia and asphyxia and those in which there was no demonstrable pathologic lesion when combined refer to deaths under 2 weeks for which the cause was determined by satisfactory necropsy.

per cent) as for deaths from intracranial hemorrhage (18.6 per cent). Such complications seem to be more important in the deaths from neonatal pneumonia (31 per cent), and less important in asphyxia (12.3 per cent). They are possibly more important in the infants who died without demonstrable pathologic lesions (24.3 per cent) than in the total deaths under 2 weeks.

(b) *Complications of Labor.*⁸—Complications of labor occurred in the mothers of 20.4 per cent of the 2,283 infants who died under 2 weeks, 17.3 per cent of the 1,401 premature infants who died under 2 weeks, 25.5 per cent of the 882 full term infants who died under 2 weeks and 8.4 per cent of the 1,109 full term infants who died between 1 and 11 months inclusive.

These differences in the percentages indicate that complications of labor are important factors in neonatal mortality in general and are more important in the deaths of full term infants than in those of premature infants.

Complications of labor occurred in the mothers of (a) 28.3 per cent of the 237 infants who died from intracranial hemorrhage, (b) 26.2 per cent of the eighty-four infants who died from pneumonia, (c) 36.9 per cent of the sixty-five infants who died from asphyxia and (d) 14.4 per cent of the 362 infants who died without demonstrable pathologic lesions.

In the deaths from intracranial hemorrhage and asphyxia, the frequency of the complications of labor is greater than the frequency of such complications in the total group of 2,283 deaths under 2 weeks. Even in the infants who died of pneumonia, complications of labor occurred with greater frequency than in the infants who died between 1 and 11 months inclusive.

(c) *Complications of Both Pregnancy and Labor.*⁹—Complications of both pregnancy and labor occurred in the mothers of 4.9 per cent of the 2,283 infants who died under 2 weeks, 2.5 per cent of the 1,401 premature infants who died under 2 weeks, 8.8 per cent of the 882 full term infants who died under 2 weeks and 0.9 per cent of the 1,109 full term infants who died between 1 and 11 months inclusive.

Obviously, complications of pregnancy and labor when they occur together are important in the production of neonatal deaths. Furthermore, complications of pregnancy and labor together seem to be more important in the deaths of full term infants than in the deaths of premature infants.

Complications of pregnancy and labor occurred together in the mothers of (a) 9.7 per cent of the 237 infants who died from intracranial hemorrhage, (b) 1.2 per cent of the eighty-four infants who died from pneumonia, (c) 10.8 per cent of the sixty-five infants who died from asphyxia and (d) 3.3 per cent of the 362 infants who died without demonstrable pathologic lesion.

Thus complications of pregnancy and labor when they occur together are particularly important in the production of deaths from intracranial hemorrhage and asphyxia and are relatively less important in the production of deaths without any demonstrable pathologic lesion and in pneumonia.

Conclusion.—The complications of pregnancy and those of labor occurring alone or together seem to be

responsible, in part at least, for deaths in infants under 2 weeks of age. The complications of pregnancy are particularly important in the production of deaths in premature infants, while the complications of labor, or combined complications of pregnancy and labor, are more liable to contribute to deaths in full term infants.

The complications of pregnancy also seem to play a part in the deaths of infants who, at necropsy, are without demonstrable pathologic lesions. Most of these infants are premature. Complications of pregnancy also are a factor in pneumonia, while the complications of labor seem to be important in the deaths from pneumonia, asphyxia and intracranial hemorrhage.

A further reduction of deaths in premature infants and deaths from pneumonia in infants under 2 weeks may be secured by providing adequate antepartum care to avoid the complications of pregnancy or, at least, by treating such complications properly and promptly. By providing skilled care during delivery, the ill effects of the complications of labor may be diminished or abolished; thus perhaps a further reduction in deaths from asphyxia and intracranial hemorrhage may be secured.

"The desirable attendant for the pregnant woman is a physician adequately trained and experienced in obstetrics and so aware of his limitations that, when emergencies arise which are beyond his competence, he will not delay in securing help."¹⁰

2. OPERATIVE PROCEDURES

Under the heading "operative procedures" are included any technics or operations exclusive of episiotomy other than those used in the conduct of normal, spontaneous labor and delivery; for example, such procedures as mechanical induction of labor, forceps delivery, version and extraction and cesarean section.

Operative procedures were employed for the mothers of 24.8 per cent of the 2,283 infants who died under 2 weeks, 18.8 per cent of the 1,401 premature infants who died under 2 weeks, 34.5 per cent of the 882 full term infants who died under 2 weeks, and 10 per cent of the 1,109 full term infants who died between 1 and 11 months inclusive.

Thus operative procedures were employed with greater frequency for the mothers of infants who died under 2 weeks than for those who died between 1 and 11 months inclusive and may be an important factor associated with neonatal deaths. Such procedures are more frequent in the neonatal deaths of full term infants than of premature infants.

Operative procedures were employed for the mothers of (a) 37.1 per cent of the 237 infants who died from intracranial hemorrhage, (b) 26.2 per cent of the eighty-four infants who died from pneumonia, (c) 41.5 per cent of the sixty-five infants who died from asphyxia and (d) 15.5 per cent of the 362 infants who died without demonstrable pathologic lesions.

Comparison of these four percentages with the 24.8 per cent of operative procedures in the total 2,283 neonatal deaths seems to indicate that operative procedures are especially frequent in association with deaths from intracranial hemorrhage and asphyxia but are not as frequent with deaths from the pneumonias or without demonstrable pathologic lesions.

8. By this we refer only to complications occurring from the onset of labor to the birth of the infant.

9. By complication of both pregnancy and labor is meant any abnormal condition occurring during pregnancy, in addition to some abnormal condition during labor.

10. Galdston, Iago: *Maternal Death: The Ways to Prevention*, New York, Commonwealth Fund, 1937, p. 32.

(a) *Operative Procedures Together with Complications of Pregnancy, of Labor or of Both.*—How often do complications of pregnancy, of labor or of both and operative procedures occur together when the infant dies under 2 weeks? Which is the more important factor in these neonatal deaths—the operative procedures or the complications?

When complications of pregnancy, of labor or of both occurred, operative procedures were employed in the delivery of 54.2 per cent of the 1,048 infants who died under 2 weeks, 40.5 per cent of the 649 premature infants who died under 2 weeks, 76.5 per cent of the 399 full term infants who died under 2 weeks and 57 per cent of the 193 full term infants who died between 1 and 11 months inclusive.

These figures indicate that, with complications of pregnancy, of labor or of both, operative procedures were employed with almost equal frequency when the infant died between 1 and 11 months inclusive as when the infants died under 2 weeks. If, however, the infants who died under 2 weeks are grouped as premature and as full term infants, mothers had complications with about the same frequency in the two groups. Operative procedures were employed much less frequently in the delivery of premature than in the delivery of full term infants. When the deaths of full term infants only who died under 2 weeks are compared with the deaths of full term infants who died between 1 and 11 months inclusive, it is found that operative procedures were employed more frequently in the delivery of infants who died under 2 weeks, the figures being 76.5 per cent and 57 per cent, respectively.

(b) *Operative Procedures Together with Complications of Pregnancy.*—Operative intervention, together with complications of pregnancy, occurred in the delivery of 23.3 per cent of the 468 infants who died under 2 weeks, 23.7 per cent of the 372 premature infants who died under 2 weeks, 21.9 per cent of the ninety-six full term infants who died under 2 weeks and 8.8 per cent of the ninety full term infants who died between 1 and 11 months inclusive.

This difference between 23.3 per cent and 8.8 per cent indicates that operative procedures together with complications of pregnancy are important in neonatal deaths.

(c) *Operative Procedures Together with Complications of Labor.*—When complications of labor only occurred, operative procedures were employed in the delivery of 76.5 per cent of the 467 infants who died under 2 weeks, 62.8 per cent of the 242 premature infants who died under 2 weeks, 91.2 per cent of the 225 full term infants who died under 2 weeks and 99 per cent of the ninety-three full term infants who died between 1 and 11 months inclusive.

Operative procedures are less often associated with deaths of premature infants under 2 weeks when there were complications of labor than they are with deaths of full term infants under 2 weeks. Furthermore, operative procedures with complications of labor seem to increase the infants' chances of surviving the neonatal period, since there was a greater proportion of operative procedures in the case of infants who died between 1 and 11 months inclusive at whose birth there were complications of labor than there was in the case of the infants who died under 2 weeks at whose birth there were complications of labor.

Conclusion.—Operative procedures in general are frequently associated with neonatal deaths and particularly with those from intracranial hemorrhage and asphyxia. In those cases in which there are complications of pregnancy, death of an infant under 2 weeks is more apt to occur if operative procedures are employed than if not employed. However, this statement must be considered with due reference to the indications for the operative procedures in the case of certain complications.

Operative procedures appear to be beneficial when employed for complications of labor; there are more neonatal deaths after complications of labor without operation than after such complications with operation. Conversely, operative procedures involve a greater risk of death in the neonatal period in cases in which complications of pregnancy occur than in instances in which delivery is permitted to occur spontaneously.

Since operative procedures for the mothers with complications of pregnancy seem to increase the hazard to the infant, careful consideration should be given before any such procedures are employed, and the indications should be duly weighed by the obstetrician. With many complications of pregnancy the operative procedures are justified despite the increased hazard to the infant, since the procedure is performed primarily in the interests of the mother.

Operative procedures for complications of labor, particularly when the infant is born at full term, seem to be a factor in reducing the hazard to the infant during the neonatal period. Since operative procedures in general, however, seem to add to the danger to the infant, only the most skilled type of obstetric technic must be employed for delivery of the infant if the child is to be given the maximum opportunity for survival.

3. SOLUTION OF POSTERIOR PITUITARY

It is generally conceded that the use of solution of posterior pituitary during the first and second stages of labor is, as a rule, hazardous for the infant.

The use of oxytocics, particularly pituitary extract, prior to delivery, is dangerous. The danger is twofold: first, to the mother, as its use has repeatedly been followed by rupture of the uterus; second, to the fetus, as many cases of stillbirth have been caused by this drug due to severe toxic uterine contractions producing violent labor which results in intracranial damage.

Pituitary extract should be considered like dynamite, useful when skilfully and intelligently used at the proper time, but otherwise very dangerous.

The child may be lost as a result of cerebral hemorrhage caused by the rapid forcing of the head into and through the birth canal, or by asphyxia due to compression of the placenta by long-continued uterine contractions.¹¹

In the cases in which the data were available, solution of posterior pituitary was given during the first or second stage of labor to the mothers of 3.5 per cent of the 2,262 infants who died under 2 weeks, 2.4 per cent of the 1,391 premature infants who died under 2 weeks, 5.3 per cent of the 871 full term infants who died under 2 weeks and 1.8 per cent of the 1,062 infants who died between 1 and 11 months inclusive.

These figures seem to show that solution of posterior pituitary was given twice as frequently to mothers of

11. *Maternal Care: The Principles of Antepartum, Intrapartum, and Postpartum Care for the Practitioner of Obstetrics*, American Committee on Maternal Welfare, Chicago, University of Chicago Press, 1937, pp. 51-52.

infants who died under 2 weeks as to mothers of full term infants who died between 1 and 11 months inclusive.

Conclusion.—The use of solution of posterior pituitary during the first and second stages of labor is contributory, at least, to neonatal deaths. It seems particularly a hazard in contributing to deaths of full term infants under 2 weeks of age.

Solution of posterior pituitary when given to mothers during the first or second stage of labor should be administered with the greatest caution and only when the indications have been determined to be proper by the obstetrician.

4. ANALGESICS

The use of analgesics has also been suggested as a possible factor in the production of deaths in infants under 2 weeks.

In the cases in which the data were available, analgesics were given to the mothers of 11.6 per cent of the 2,260 infants who died under 2 weeks, 11.1 per cent of the 1,389 premature infants who died under 2 weeks, 12.5 per cent of the 871 full term infants who died under 2 weeks and 3.1 per cent of the 1,061 infants who died between 1 and 11 months inclusive.

Analgesics were given almost four times as frequently to the mothers of infants who died under 2 weeks as to the mothers of those who died between 1 and 11 months inclusive.

Analgesics were given to the mothers of (a) 12 per cent of the 234 infants who died from intracranial hemorrhage, (b) 9.5 per cent of the eighty-four infants who died from pneumonia, (c) 18.5 per cent of the sixty-five infants who died from asphyxia and (d) 11.7 per cent of the 359 infants who died without demonstrable pathologic lesions.

The administration of analgesics to the mother seems to be more frequent in association with deaths from asphyxia than in association with deaths from all causes in infants under 2 weeks. However, the difference is less than twice the standard error.

Conclusion.—The use of analgesics is an important factor associated with neonatal deaths and may be important in the deaths due to asphyxia. Physicians should bear in mind the threat to the life of the infant produced by the injudicious use of analgesics and not permit the mother's demands for "painless childbirth" to outweigh their good judgment to the degree that they employ drugs to alleviate pain at risk to the infant's life.

5. DRY LABOR

Information concerning dry labor was available for only a part of those deaths occurring during 1937. It was not coded during 1936.

Dry labor occurred in the mothers of 6.3 per cent of the 1,138 infants who died under 2 weeks, 6.3 per cent of the 702 premature infants who died under 2 weeks and 0.4 per cent of the 516 infants who died between 1 and 11 months inclusive.

The frequency of dry labor is greater in association with the deaths of infants under 2 weeks than in association with those of infants between 1 and 11 months inclusive.

Dry labor was present in the mothers of (a) 10 per cent of the 130 infants who died from intracranial hemorrhage, (b) 4.4 per cent of the forty-six infants who died from pneumonia, (c) 5.8 per cent of the fifty-

two infants who died from asphyxia and (d) 5.5 per cent of the 236 infants who died without demonstrable pathologic lesions.

The frequency of dry labor seems to be greater in association with deaths from intracranial hemorrhage than in association with all neonatal deaths. However, the difference is not quite three times the standard error.

Conclusion.—Dry labor may be a factor in the production of neonatal deaths and particularly of those from intracranial hemorrhage. Artificial rupture of the membranes should be done only when indicated and dry labors conducted as skilfully as possible.

6. BREECH PRESENTATION

Breech presentation occurred in the case of 15 per cent of the 2,283 infants who died under 2 weeks, 17.3 per cent of the 1,401 premature infants who died under 2 weeks, 11.3 per cent of the 882 full term infants who died under 2 weeks and 3.4 per cent of the 1,109 full term infants who died between 1 and 11 months inclusive.

Breech presentation occurred with much greater frequency in association with the deaths of infants under 2 weeks than in association with those of infants between 1 and 11 months inclusive.

Breech presentation occurred in the case of (a) 15.4 per cent of the 237 infants who died from intracranial hemorrhage, (b) 10.7 per cent of the eighty-four infants who died from pneumonia, (c) 15.4 per cent of the sixty-five infants who died from asphyxia and (d) 17.1 per cent of the 362 infants who died without demonstrable pathologic lesions.

Breech presentation seems to occur with about the same frequency in association with deaths of infants without demonstrable pathologic lesions, with deaths from asphyxia and intracranial hemorrhage and with deaths from all causes in infants under 2 weeks.

Conclusion.—Breech presentation is a significant factor in the neonatal deaths, especially in neonatal deaths of prematurely born infants.

Breech presentation occurs with greater frequency in the case of premature infants than in the case of full term infants, and the general neonatal mortality is much higher for premature infants than for full term infants. But even in the case of deaths of full term infants under 2 weeks, breech presentation occurred with three times the frequency of its occurrence with the deaths in infants between 1 and 11 months inclusive. Since breech presentation is a factor in these deaths, the need is apparent for especially skilled obstetric care in breech deliveries in order to reduce mortality.

7. MULTIPLE BIRTHS

The births were multiple for 9 per cent of the 2,283 infants who died under 2 weeks, 13.5 per cent of the 1,401 premature infants who died under 2 weeks, 2.2 per cent of the 882 full term infants who died under 2 weeks and 2.6 per cent of the 1,109 infants who died between 1 and 11 months inclusive.

The frequency of multiple births is greater for infants who died under 2 weeks than for those who died between 1 and 11 months inclusive. This difference is produced particularly by the premature infants.

The births were multiple for (a) 7.2 per cent of the 237 infants who died from intracranial hemorrhage, (b) 3.6 per cent of the eighty-four infants who died

from pneumonia, (c) 9.2 per cent of the sixty-five infants who died from asphyxia and (d) 17.4 per cent of the 362 infants who died without demonstrable pathologic lesions.

The percentage of infants who died under 2 weeks without demonstrable pathologic lesions (which group is made up mostly of premature infants) is twice as high as the percentage of deaths of twins and triplets in the group of 2,283 infants who died under 2 weeks.

Conclusion.—Twins or triplets contribute greatly to neonatal mortality because of the large number of multiple pregnancies that terminate prematurely and apparently not because of any other particular condition associated with twins and triplets. That this is probably true is shown by the fact that the number of full term twins who died under 2 weeks is slightly less than the number of full term twins who died between 1 and 11 months inclusive. In other words, a greater percentage of full term twins survive the neonatal period than die, while the reverse is true in the case of premature infants.

Twins or triplets who die during the neonatal period frequently are without demonstrable pathologic lesions. Every possible effort should be made to diagnose multiple pregnancy as early as possible and to use all available methods to prevent its early termination.

"It is generally believed that the second-born twin dies much more often than the first. Our figures show that in 1937 forty-six first-born and sixty-two second-born twins died neonatally.

8. ANTEPARTUM CARE

Most obstetricians believe that adequate antepartum care is a factor in the prevention of both maternal and neonatal mortality. A medical investigator specially trained in this type of work made a personal inquiry to determine in how many cases in which the infant died the mother had adequate antepartum care and then judged whether the care was adequate or inadequate.¹²

Errors may occur in this type of survey because there is no way to check the accuracy of the statements made to the investigator. However, the data seem sufficiently reliable to warrant certain conclusions.

In the cases in which the data were available, there was inadequate or no antepartum care for the mothers of 37.9 per cent of the 2,260 infants who died under 2 weeks, 41.3 per cent of the 1,389 premature infants who died under 2 weeks, 32.5 per cent of the 871 full term infants who died under 2 weeks and 44.9 per cent of the 1,109 infants who died between 1 and 11 months inclusive.

A smaller percentage of mothers of infants who died between 1 and 11 months inclusive received adequate antepartum care than of mothers of those who died under 2 weeks. The percentage of mothers of premature infants who died under 2 weeks who received adequate antepartum care was less than the percentage of mothers of full term infants who died under 2 weeks who received such care.

These figures may seem contradictory. They indicate that one effect of antepartum care is to increase the like-

lihood of carrying gestation to term and, in this way, to improve the infant's chance of survival beyond the neonatal period.

They indicate also, however, that the less antepartum care the mother had the greater were the chances of the infant's surviving the neonatal period. This cannot be true if antepartum care is of any value. Therefore, there must be factors producing neonatal mortality which are not eliminated by antepartum care. In other words, factors enter into these cases which counteract or overcome the benefits derived from proper supervision and management of pregnancy.

To prove that such factors exist, it is necessary to remember that they would appear in the tabulation of deaths with the same frequency as antepartum care; that is, they would occur less frequently for the premature than for the full term infants who died under 2 weeks and still less frequently for the full term infants who died between 1 and 11 months inclusive.

Of the factors examined in this investigation, the use of solution of posterior pituitary before the end of the second stage of labor, complications of labor and operative procedures are shown to occur with the same frequency as adequate antepartum care; that is, they seem less frequent for the premature than for the full term infants who died under 2 weeks and still less frequent for the full term infants who died between 1 and 11 months inclusive. The expected benefits of adequate antepartum care may be offset for the full term infants dying neonatally by injudicious or unindicated procedures during labor or delivery, by complications of labor, by the use of solution of posterior pituitary before the termination of the second stage or by improper operative procedures.

Conclusion.—Antepartum care is valuable because it probably aids in the prevention of prematurity. However, the value of antepartum care may be entirely lost as the result of injudicious procedures or faulty technic at the time of labor. Hence the infant is given the best chance for surviving if the mother receives adequate antepartum care with skilled care during delivery and all injudicious procedures are strictly avoided.

9. PARITY

Of 726 premature infants who died under 2 weeks during 1937, the parity of the mother was known for 714. Of the 440 full term infants who died under 2 weeks during 1937, the parity of the mother was known for 436, a total of 1,150 infants who died under 2 weeks. Of the 545 full term infants who died between 1 and 11 months inclusive during 1937, the parity of the mother was known for 520.

In the cases in which the parity of the mother was known, a primipara was the mother of 44 per cent of the 1,150 infants who died under 2 weeks, of 42 per cent of the 714 premature infants who died under 2 weeks, of 47 per cent of the 436 full term infants who died under 2 weeks and of 32 per cent of the 520 full term infants who died between 1 and 11 months inclusive.

Primiparity occurred with greater frequency in mothers of infants who died under 2 weeks than in mothers of those who died between 1 and 11 months inclusive.

In cases in which the parity was known, a primipara was the mother of (a) 53 per cent of the 135 infants who died from intracranial hemorrhage, (b) 33 per

12. Our criteria for adequate antepartum care in general followed the standards of the Children's Bureau and included supervision over the condition of the mother beginning not later than the fifth month of gestation, periodic blood pressure readings, regular chemical and microscopic examinations of the urine, Wassermann or Kahn tests, the taking of internal pelvic measurements, determination of the position of the fetus and the existence of heart tones, a complete physical examination, attention to diet and elimination, and advice as to exercise, work, recreation and rest.

cent of the forty-six infants who died from pneumonia, (c) 46 per cent of the fifty-two infants who died from asphyxia and (d) 40 per cent of the 239 infants who died without demonstrable pathologic lesions.

A greater percentage of mothers of infants who died of intracranial hemorrhage were primiparas than of mothers of all infants who died under 2 weeks.

The frequency of primiparity was about the same for mothers of infants who died from asphyxia and for those who died without demonstrable pathologic lesions as for mothers of all infants who died under 2 weeks.

(a) *Parity and Complications of Pregnancy, of Labor or of Both.*—Complications of pregnancy, of labor or of both occurred in the mothers of 57.5 per cent of the 205 full term infants who died under 2 weeks who were primiparas, in the mothers of 42.5 per cent of the 231 full term infants who died under 2 weeks who were multiparas, in the mothers of 31 per cent of the 164 full term infants who died between 1 and 11 months inclusive who were primiparas, and in the mothers of 17.7 per cent of 356 full term infants who died between 1 and 11 months inclusive who were multiparas.

These are significant differences and indicate that primiparas definitely have more complications than do multiparas.

(b) *Parity and Complications of Labor.*—Complications of labor occurred in the mothers of 41 per cent of the 205 full term infants who died in the first two weeks who were primiparas, in the mothers of 22.7 per cent of the 231 full term infants who died under 2 weeks who were multiparas, in the mothers of 15.8 per cent of the 164 full term infants who died between 1 and 11 months inclusive who were primiparas and in the mothers of 5.9 per cent of the 356 full term infants who died between 1 and 11 months inclusive who were multiparas.

There is a greater proportion of complications of labor in primiparas than in multiparas.

Of the 220 infants who died under 2 weeks whose mothers did not have complications, (a) for 39.6 per cent the mother was a primipara and (b) for 60.4 per cent the mother was a multipara.

Of the 406 infants who died between 1 and 11 months inclusive whose mothers did not have complications, (a) for 27.8 per cent the mother was a primipara and (b) for 72.2 per cent the mother was a multipara.

The difference between 39.6 per cent and 27.8 per cent is worthy of note and probably not accidental. In the case of primiparas even without complications there is a definitely greater hazard to the life of the infant during the neonatal period.

(c) *Parity and Operative Procedures.*—Of the mothers whose infants died in the first two weeks, operative procedures were employed for (a) 49.5 per cent of the 205 primiparas and (b) 26 per cent of the 231 multiparas.

This again is a noteworthy difference, indicating that operative procedures are a definite factor in the production of deaths in infants under 2 weeks whose mothers are primiparas.

Conclusion.—In the case of primiparas without complications, there is during the first two weeks a definitely greater hazard to the life of the infant than in the case of multiparas without complications; primiparas have more complications, particularly complications of labor, than do multiparas; operative procedures are employed more often for primiparas than for multiparas. This

points out again the need for most skilled obstetric care, particularly in the delivery of primiparas in the presence of complications, in order further to reduce neonatal mortality.

10. SEROLOGIC TESTS FOR SYPHILIS

In the case of the 1,401 premature and 882 full term infants who died neonatally, the serologic test for syphilis was done for 885 and 572 of the mothers, respectively. The serologic test was positive for the mothers of 3.4 per cent of the 1,437 infants who died under 2 weeks, 4.2 per cent of the 885 premature infants who died under 2 weeks, 2.1 per cent of the 572 full term infants who died under 2 weeks and 3.8 per cent of the 705 infants who died between 1 and 11 months inclusive.

The difference in the percentage of positive serologic tests between the mothers of the premature and those of full term infants dying neonatally is only 2.8 times the standard error. There is little difference in the frequency of positive serologic tests between mothers of infants who died under 2 weeks and those of infants who died between 1 and 11 months inclusive. We may assume, therefore, that a positive serologic test is more often associated with the neonatal death of premature infants than of full term infants.

Conclusion.—Even though our figures do not show syphilis to be a great factor in neonatal deaths, every pregnant woman should have a serologic examination for syphilis as early as possible in pregnancy and adequate treatment should be given in all cases of a positive reaction. Some reduction in neonatal mortality, particularly for premature infants, should result.

COMMENT

In listing causes of death in the neonatal period as determined by satisfactory necropsy, the largest group is that in which there was no demonstrable pathologic lesion; then follow those in which there was intracranial hemorrhage, pneumonia and asphyxia, respectively.

A reduction of neonatal mortality to any material degree demands attack on those conditions which our figures seem to show are most important in contributing directly or indirectly to the causes of death.

I. *No Demonstrable Pathologic Lesion.*—The following factors are of special importance in contributing to the deaths of infants under 2 weeks in whom demonstrable pathologic lesions are not found: (a) prematurity, (b) complications of pregnancy, (c) breech presentation and (d) multiple births.

If the deaths of infants without demonstrable pathologic lesions are to be prevented, an effort must be directed particularly toward the prevention of prematurity, toward providing the best possible care for complications of pregnancy and toward providing the most skilled care during delivery in abnormal presentations.

The true cause of death in the group of infants without any demonstrable pathologic lesion is not yet determined in many cases. Since the majority of these infants are viable, the prematurity itself is probably not entirely responsible.

(a) *Prematurity:* Further studies are necessary to determine exactly what factors produce death in viable premature infants. Possibly some pathologic lesion not yet demonstrated by methods now known may be a factor that contributes to the deaths in this group.

In our series of cases these premature infants were promptly put into an incubator, were supplied with

oxygen and were constantly given the type of special care that is accepted as necessary and satisfactory for prematurely born infants whether they are at home or in the hospital. Consequently we do not believe that lack of the best known care is responsible for the deaths in our series of premature infants without demonstrable pathologic lesions.

Among the complications most often leading to premature births are (1) toxemia, (2) external violence, such as accidents to the mother, (3) placenta praevia and (4) undetermined causes. These factors lead to birth before term, either by producing spontaneous expulsion of the fetus or because the emergency nature of the condition is often an indication for intervention.

In the prevention of prematurity from toxemia and external violence, as well as from other causes, provision of the best possible antepartum care may be of some aid. Some experimental work indicates that the use of vitamin E and progesterin beginning in the early months of pregnancy may aid in the prevention of prematurity in that large group of cases in which the cause of prematurity is undetermined and even perhaps in some instances of premature separation of the placenta. Further studies are needed to determine the exact value of these preparations.

Other things being equal, the infant's chances of survival increase with the period of gestation up to term. To the extent to which prematurity may be prevented or diminished, neonatal mortality will be reduced.

(b) *Complications of Pregnancy:* To cope with the complications of pregnancy, also, adequate antepartum care seems to be the most hopeful effort.

(c) *Breech Presentation:* In breech deliveries, a common cause of death is anoxemia (lack of oxygen in the blood), which in many instances occurs without producing any definite pathologic lesions. It is well known that breech deliveries occur more often with premature births than with full term births, which may account in part for the mortality due to breech deliveries of infants without any demonstrable pathologic lesion. The provision of the best possible obstetric care during delivery in cases of breech presentation may result in reduced mortality from this cause.

(d) *Multiple Births:* Perhaps the use of progesterin, wheat germ oil or normal pregnancy serum in cases of multiple pregnancy may serve to prolong the pregnancy and thus improve the chances of survival of the infants. Our figures do not show that there is anything inherent in multiple pregnancies that may lead to death of the infants other than the fact that these pregnancies often terminate prematurely.

II. *Intracranial Hemorrhage.*—Our figures appear to show that the following factors are of special importance in contributing to the deaths of infants under 2 weeks from intracranial hemorrhage; (a) operative procedures, (b) breech presentation, (c) complications of labor, accompanied by operative procedures, and (d) primiparity.

If the deaths of infants from intracranial hemorrhage are to be prevented, effort must be directed particularly toward providing the most skilled type of obstetric care during labor and delivery, since the factors which are most important in contributing to these deaths, that is, operative procedures, breech presentation, complications of labor and primiparity, are directly connected with the delivery of the infant. Our analysis has revealed that even with the best type of antepartum care

the complications of labor with unskilled operative procedures or the use of unindicated operative procedures may diminish or nullify the value of efforts exerted in behalf of the mother and infant throughout pregnancy.

In specific instances, preventable factors, such as the questionable use of high forceps, depressed fracture following forceps and the injudicious use of solution of posterior pituitary, were found to be associated with deaths from intracranial hemorrhage.

While skill in the conduct of labor will not prevent all deaths from intracranial hemorrhage, it should aid materially in reducing the number.

III. *Pneumonia.*—Our studies seem to indicate that the following factors are of special importance in contributing to the deaths of infants under 2 weeks from pneumonia: (a) complications of labor and pregnancy and (b) prematurity. Hence better obstetric care, both antepartum and intrapartum, should aid in the reduction of the number of deaths from this cause, since it will help prevent complications of pregnancy and labor, and prematurity.

There are probably other factors responsible for deaths from pneumonia in infants under 2 weeks with which our present study was not concerned. We refer specifically to the care given infants immediately after birth in nurseries for the newborn. The establishment of aseptic nursery technic, the prevention of contact between newborn infants and individuals not concerned with their care, may aid in reducing the number of deaths from pneumonia in infants under 2 weeks. Experimental work now being conducted on air conditioning of nurseries and the use of ultraviolet irradiation to aid in the prevention of air-borne infections may bring to light other means of reducing deaths from pneumonia.

IV. *Asphyxia.*—The figures appear to show that the following factors are of special importance in contributing to deaths of infants under 2 weeks from asphyxia: (a) breech presentation, (b) the use of analgesics and (c) operative procedures because of fetal or maternal disproportion.

If the deaths of infants from asphyxia are to be prevented, effort must be directed particularly toward improvement in care given at the time of delivery. Death from asphyxia seems to occur, in the complicated cases, especially with breech deliveries; such cases deserve the most skilled obstetric care.

Avoidance of unnecessary use of analgesics should also be beneficial.

It is interesting to note that 20 per cent of the deaths from asphyxia were in infants delivered by cesarean section. More skilful technic in cesarean operations and the avoidance of them when they are not indicated would reduce the mortality from this cause.

SUMMARY

A large number of factors contributing to deaths of infants under 2 weeks, and particularly those under 1 day of age, may be controlled by the knowledge now available. Improvement in obstetric care, both antepartum and postpartum, better hospital nursery care, the avoidance of dangerous procedures and injudicious use of drugs, which figures show to be definitely hazardous, the use of measures to prolong pregnancy to term, such as progesterin and vitamin E, and the employment of proper methods of resuscitation, should bring a definite reduction in neonatal mortality.

THE SIGNIFICANCE OF THE POSITIVE
KLINE EXCLUSION TEST

UNCONFIRMED BY THE KOLMER OR KAHN TEST

RUTH M. MYERS, M.S.

AND

C. A. PERRY, D.Sc.

BALTIMORE

In 1926 Kline and Young¹ published their first report of a microscopic slide precipitation test for the detection of syphilis. In subsequent reports,² modifications were given which were directed mostly toward the preparation of a more sensitive antigen and more stable antigen emulsion. At present the Kline test is used in two forms: one, with "very sensitive" antigen emulsion, designated as the Kline exclusion test; the other, with a "sensitive" antigen emulsion, designated as the Kline diagnostic test. These tests are easily and rapidly performed, are comparatively inexpensive and require but little equipment.

The Bureau of Bacteriology of the Maryland State Department of Health became interested in the Kline exclusion test while seeking a simple yet reliable screen test, by which to exclude as negative many of the routine specimens submitted for the serodiagnosis of syphilis. Reports in the literature indicated that the Kline exclusion test was highly sensitive but also somewhat nonspecific.³ Most of these reports were based on large series of tests on routine specimens. In the majority, analyses were made on the basis of agreement or disagreement with other tests such as the Kahn or the Kolmer-Wassermann. In some, accurate clinical information was available. In one, evaluation was attempted by sending questionnaires to the individual physicians.

In the Maryland laboratories a series of tests was carried out in triplicate on approximately 500 specimens in a preliminary attempt at evaluation of the Kline exclusion test. In this series the primary concern was the determination of the incidence of Kahn or Kolmer reactions, in the absence of Kline exclusion reactions. This incidence was found to be very slight. Of 272 specimens with negative Kline exclusion reactions, one was unsatisfactory for examination by either the Kolmer or the Kahn test and two gave doubtful Kolmer reactions. One of these doubtful Kolmer specimens came from a treated patient, the other had been submitted for diagnosis. Neither case was checked by a second specimen. None of the remaining 269 Kline exclusion negative specimens reacted in any degree to the Kolmer or to the Kahn test. Since no positive Kolmer or Kahn reaction was obtained when the Kline exclusion test was negative, it seemed that the Kline exclusion was a satisfactory screen test and the routine use of it for this purpose was adopted. It may be added

that every one of 200 more specimens tested at various intervals has also been found to give negative Kline exclusion, Kolmer and Kahn reactions. In another series in which the Hinton and Kline exclusion tests were performed in parallel, none of 401 specimens which were Kline exclusion negative were Hinton positive or doubtful.

From the beginning of our experience with the Kline exclusion test it was noticed that a number of positive Kline exclusion reactions were accompanied by negative Kolmer and Kahn reactions. Since reports in the literature have indicated that many specimens which are positive to the Kline exclusion test and negative to other tests are indicative of syphilis, and since the recent evaluation studies of the United States Public Health Service⁴ have indicated a high degree of specificity for this test, such reactions were first reported to physicians as doubtful. It was hoped, thereby, that certain cases would receive further clinical and laboratory study before being dismissed as nonsyphilitic and that certain syphilitic infections would not be missed.

Check specimens were submitted from a number of these cases. In many instances the reaction was persistently positive; in just as many others the reaction was decidedly diminished or frankly negative. In a few the Kolmer or Kahn test was found to give a reaction as well as the Kline exclusion. Because these check results seemed so varied, it was decided to disregard entirely any positive or doubtful Kline exclusion reactions accompanied by negative Kolmer and Kahn reactions until a more careful consideration of the problem could be undertaken. Accordingly, specimens giving such reactions were reported as negative.

In an effort to determine whether or not these positive Kline exclusion reactions accompanied by negative Kolmer and Kahn reactions were really significant, questionnaires were prepared and sent to each physician who had submitted such a specimen. Of 15,033 specimens submitted for diagnosis over a period of about seven months, there were 540, or 3.6 per cent, which were positive to the Kline exclusion test and negative to both the Kolmer and Kahn tests. These 540 specimens were divided as to the report given the physician. In 275 of them, representing 200 cases, the report was given as "doubtful serologic test." In the remaining 265, representing 253 cases, the report was given as negative. Of the 200 cases given doubtful reports, seventy-two, or 36 per cent, were checked by repeat specimens. Among the 253 cases given negative reports only twenty-two, or 8.7 per cent, were checked. Thus, when doubtful reports were sent out, physicians submitted four times as many check specimens as when negative reports were sent out. A few additional check specimens were received along with replies to questionnaires. Response to the questionnaires likewise differed in these two groups. In the 200 "doubtful" cases, replies were received from 72 per cent, whereas, in the 253 "negative" cases, replies were received from only 31.6 per cent. There was no evidence at any time to indicate that any physician interpreted "doubtful" as "positive."

The results on the repeat specimens in 157 checked cases of both groups were as shown in table 1.

Inform.* 16: 189 (June) 1935. Parran, Thomas; Hazen, H. H.; Sanford, A. H.; Seneff, F. E.; Simpson, W. M., and Vonderlehr, R. A.: The Efficiency of State and Local Laboratories in the Performance of Serodiagnostic Tests for Syphilis, *ibid.* 18: 4 (Jan.) 1937. Parran, Thomas; Hazen, H. H.; Mahoney, J. F.; Sanford, A. H.; Seneff, F. E.; Simpson, W. M., and Vonderlehr, R. A.: A Comparative Study of Serodiagnostic Tests for Syphilis as Performed by Thirty-Nine State Laboratories, *ibid.* 18: 273 (Aug.) 1937.

It appears that in nine of the 157 cases checked, or 5.7 per cent, the original Kline exclusion positive result was probably significant, since in later specimens this result was supported by a positive Kolmer or Kahn test and since the specificity of these two tests in our laboratory is very high. Two of these cases were indicated as primary syphilis, two as tertiary. Another primary case not included in this summary because check specimens were not sent to us later became Wassermann and Kahn positive at the Walter Reed Hospital in Washington. It would seem also that in fifteen additional cases, or 9.6 per cent, the original Kline exclusion positive test may have been significant, since in second specimens the Kahn or the Kolmer test was doubtful. In this group syphilis was indicated by the physicians in six cases.

The diagnoses given by the physicians for 234 cases in which the original specimens gave positive Kline exclusion results with negative Kolmer and Kahn results are given in table 2.

Thus in twenty-six, or 11.1 per cent, of the 234 cases syphilis was definitely indicated and in sixteen, or 6.8 per cent, the possibility was admitted.

To the laboratory worker it seems that the 5.7 per cent and 9.6 per cent of original Kline exclusion positive reactions later supported by positive or doubtful Kolmer or Kahn reactions and the 11.1 per cent definite and 6.8 per cent possible syphilis as determined by physical diagnosis are certainly significant. It seems also that the physician may be interested in having the information, but with the warning that diagnostic tests are negative and only a supersensitive test positive,

doubtful report elicits further clinical consideration and serologic check-up.

3. No evidence was found to indicate that doubtful reports were interpreted as positive.

4. Therefore a report giving some indication of the reaction of the very sensitive Kline exclusion test would seem to be an advantage to the patient and an aid to the physician.

Clinical Notes, Suggestions and New Instruments

PREVENTION OF GONORRHEAL OPTHALMIA IN THE NEWBORN

A. J. SKEEL, M.D., CLEVELAND
Director of Obstetrics, St. Luke's Hospital

In 1935 Lehrfeld¹ reported the results of a study of ophthalmia neonatorum in Philadelphia. He concluded that the incidence of this condition has not materially diminished in fifteen years and quoted Mayou as authority for the statement that in London there was only slight improvement in a similar period. In 27,873 newborn infants in six Philadelphia hospitals he found 632 cases of ophthalmia, in 28 per cent of which the condition was gonorrheal, an incidence of one case of gonorrheal ophthalmia to every 158 births.

In Cleveland in 1933 at four hospitals having 4,354 deliveries, gonorrheal ophthalmia developed in eighteen cases. In the same hospitals in 1935, with 4,637 births, there were thirteen cases. This represents a total of 8,991 births with thirty-one cases of gonorrheal ophthalmia, an incidence of one in 290.

In the present communication I present the experience at St. Luke's Hospital, the technic which my associates and I have developed and the results of this technic in over 10,000 successive deliveries. St. Luke's is a private hospital, maintaining about 15 per cent of free work for training of the house staff. The remainder of the deliveries are divided about equally between a group of half a dozen specialists and seventy-five general practitioners. Most of the nonpaying patients come through the antepartum clinic, and those with gonorrheal infection are rigorously excluded. The infants are therefore not exposed as freely as in some hospitals to the risks of gonorrheal infection.

Our present technic for care of the eyes of the newborn has been in use for about ten years. It was arrived at after extensive trial of various modifications of and departures from the original Credé method. I will mention some of these briefly and state the reasons for dissatisfaction with our earlier methods.

The original method of Credé, relying as it did on 1 drop of 2 per cent solution of silver nitrate, dispensed with a glass rod to insure uniformity in the size of the drop, produced silver conjunctivitis in many cases without eliminating all gonorrheal ophthalmia. Although we exercised the utmost care, infection occurred in about 0.5 per cent of our cases.

When we followed the application of silver nitrate with a saline irrigation after two minutes, we found more cases of gonorrheal infection, although the silver conjunctivitis diminished. We tried 2 or 3 drops of 1 per cent silver nitrate with and without subsequent saline irrigation. In the one instance the cases of irritation increased and in the other incidence of gonorrheal ophthalmia was larger. Flushing the eyes with several drops of 0.5 per cent silver solution with and without subsequent saline irrigation gave equally unsatisfactory results.

Other variations were tried, and we finally arrived at our present technic by a process of trial and error. We have used this procedure in over 10,000 successive cases in which gonorrheal ophthalmia was totally eliminated. In the last 3,000 deliveries the patient has been given every twelve hours during labor prophylactic vaginal injections of an aqueous solution of merthiolate, two parts of distilled water to one part of merthio-

and with the understanding that a very careful clinical examination and check-up is indicated as well as subsequent serologic tests. This matter has been discussed with physicians who favor such a policy, but many others feel that only harm could result from it. Because we believe that a public health laboratory should be conservative, we are continuing to disregard the unconfirmed positive Kline exclusion result in reporting to the physicians until they themselves express the desire for a report indicating supersensitive results.

SUMMARY AND CONCLUSIONS

1. It was shown that in definite instances the positive Kline exclusion test unconfirmed by the Kolmer or the Kahn test is significant of syphilitic infection.

2. It was shown that physicians tend to accept without question the negative serologic report, whereas a

late solution. This was done with no thought of gonorrheal infection but may have offered some protection.

Our routine procedure is as follows:

1. At the time of delivery of the head, the eyes are carefully cleansed with dry sterile sponges. No boric acid solution is used.
2. When the cord has been cut, 3 or 4 drops of 0.5 per cent solution of silver nitrate are instilled and the lids are gently manipulated to distribute the solution to every part of the conjunctival sac. After forty-five seconds the sac is freely flushed with a 20 per cent solution of mild silver protein. This irrigation is repeated on three successive days as a routine part of the nursery technic. The substance must be completely dissolved. The solution is prepared twice weekly.

We think that the repeated conjunctival flushing with a bland silver preparation is vital to the success of the method. Our rationale of this technic is as follows:

1. Irrigation with a boric acid solution is not used; this solution is not a gonococcicide, and its use serves merely to introduce the organisms into the conjunctival sac.
2. We believe that the occasional late infection which was observed before the use of repeated irrigations with bland silver solution occurred as the result of the presence of a few organisms of reduced virulence, which are destroyed by the successive treatments.

We realize our relative freedom from cases of virulent gonorrheal vaginitis. The technic is presented in the hope that more extensive trial may be made of the procedure and its value determined.

Special Article

THE PHARMACOLOGY AND THERAPEUTICS OF VITAMIN A

S. W. CLAUSEN, M.D.
ROCHESTER, N. Y.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—ED.

Treatment with vitamin A is indicated in disorders clearly due to deficiency of vitamin A in the diet. These disorders include nutritional night blindness, xerophthalmia, keratomalacia and a definite kind of follicular keratosis of the skin. The use of vitamin A in the prophylaxis of these disorders is also well established. It is appropriate to discuss these well defined uses of vitamin A before undertaking an analysis of the other uses proposed for vitamin A. Tests for loss of adaptation to dim light have been introduced recently as a measure of deficiency of vitamin A. These tests are considered in the section of this review dealing with night blindness.

Treatment with vitamin A has been suggested in conditions obviously not due to deficiency, for example, in hyperthyroidism, because experiments with animals demonstrate an antagonism between vitamin A and thyroxine. Vitamin A has also been used for the local treatment of injuries of the skin because of a supposed stimulating effect on epithelial growth. Vitamin A has been used in conditions which

might be associated with deficiency of a moderate degree, but almost without exception the observers provided no evidence of the existence of the moderate deficiency. These conditions include urinary lithiasis and degenerative changes in the nervous system. As a rule, the evidence of benefit from the use of vitamin A in these conditions has been conflicting. The experiments with animals have not given uniformly positive results because the conditions of the experiments have been too varied. Although it cannot be concluded that deficiency of vitamin A is the sole cause of nervous degeneration or of lithiasis, it may be admitted that these abnormal conditions may be due to faulty diet, and there is hope that the exact dietary causes will be disclosed eventually.

Most observers find that severe deficiency of vitamin A is accompanied by decrease of resistance to infection. Vitamin A has been rather widely advocated to increase resistance to infection. The clinical evidence often fails to meet the requirements of statistics. Few of the observers have attempted to demonstrate the presence of vitamin A deficiency in their subjects.

Injury to animals results from large doses of vitamin A. These doses are far larger than any proposed for human beings. Ordinary doses of cod liver oil may be harmful to animals consuming unusual diets, especially herbivora. The injurious effects, at least in herbivora, are not due to the presence of vitamin A in the oil. Clinical experience would indicate that ordinary doses of fish liver oils are not injurious to human beings.

VITAMIN A AND THE EYE

Night Blindness.—Loss of visual acuity in dim light is known as night blindness. It occurs in various diseases of the eye such as toxic amblyopia, retinitis pigmentosa and detachment of the retina, but a form was known in the time of ancient Egypt which could be cured by a diet of liver. In more recent times, night blindness has been reported in prisoners, in Negro slaves in Brazil, in sailors on long voyages, in soldiers during the World War, and in Orthodox Russians during the Lenten fasts. Blegvad¹ found it in thirty-seven Danish cases of xerophthalmia. Ishihara² cured it with cod liver oil. Bloch³ suggested that it is due to deficiency of vitamin A, which, in 1921, on purely clinical grounds, he distinguished from the antirachitic factor. Parinaud⁴ suggested that visual adaptation to dim light is a function of visual purple in the retina. Because of these observations, Fridericia and Holm⁵ and Holm⁶ studied the formation of visual purple in the retinas of rats which received diets deficient in vitamin A. They found that the rate of regeneration of visual purple after its bleaching by a bright light in the living animal was less in the rats receiving the deficient diet than in the controls. The rats with deficient diet were also night blind. Tansley⁷ confirmed

these observations. Yudkin, Kriss and Smith⁸ showed that the fat extracted from the retina is one of the richest sources of vitamin A and suggested that visual purple may bear a direct structural relationship to vitamin A. Wald⁹ has shown that, in mammals, birds, amphibians and certain marine fish, vitamin A unites in the retina with a protein to form visual purple. This process takes place continuously and depends on a sufficient supply of vitamin A. Under the influence of light, visual purple is changed to visual yellow; a portion of the visual yellow reverts, in the dark, to visual purple; another portion undergoes decomposition into vitamin A and a protein. It is apparent that vitamin A takes part in a cycle of changes in the retina and that the rate of formation of visual purple after exposure of the retina to bright light depends on the available supply of vitamin A. The chemical processes involved in vision are the subjects of active study at the present time (Mirsky,¹⁰ Hecht,¹¹ Dartnall and Goodeve,¹² the von Jancsó¹³).

The facts just presented, together with the observation that night blindness is an early symptom of deficiency of vitamin A, form the basis of recent tests for visual adaptation in dim light as methods for the diagnosis of vitamin A deficiency. Hart, Mead and Guilbert¹⁴ observed spontaneous night blindness in cattle during a severe drought and proved that the visual defect was due to the very low carotene content of the food. By means of accurate clinical observations of the symptom night blindness and by analyses of the organs and of the rations for vitamin A and for carotene, their subsequent studies¹⁵ have shown that night blindness occurs only when the stores of vitamin A in the liver are practically exhausted; the daily requirement of carotene for cattle, sheep and swine depends only on the weight of the animals and does not depend on the rate of growth, the dose being from 25 to 39 micrograms per kilogram of body weight. This amount agrees closely with that found for the rat (25 micrograms per kilogram daily) by Baumann, Riising and Steenbock.¹⁶ When vitamin A is given as cod liver oil, the requirements are the same for the different species of animal and depend only on the weight. The authors give provisional figures of from 5.6 to 8.4 micrograms per kilogram of body weight for the daily requirement of vitamin A.

Studies of dark adaptation in children have been carried out by Jeans and his colleagues,¹⁷ who used at first the Birch-Hirschfeld photometer and later an improved photometer. In their method the subject is placed in the dark for ten minutes and then exposed to bright light for three minutes. During the following ten minute period of recovery, tests for visual acuity are made. The subject must be able to cooperate by stating accurately what he sees. Normal standards were obtained by testing persons known to have been eating diets rich in vitamin A. Jeans reported in 1933 that 25 per cent of rural children and 53 per cent of city children showed poor visual adaptation; later, in a smaller series, about the same incidence was found. The administration of cod liver oil or of carotene equivalent to from 5,000 to 6,000 international units of vitamin A daily brought about recovery in from four to six weeks. The minimum daily requirements for vitamin A in two boys 11 years of age were found to be about 3,000 units. Snelling at first¹⁸ agreed with the results of Jeans but later¹⁹ encountered technical difficulties in using the Birch-Hirschfeld apparatus and stated his belief that experience with the test by the subject might account for some of the "improvement" in readings following the use of cod liver oil. Palmer and Blumberg²⁰ have presented convincing evidence that improvement in visual acuity with repetition of the test may be due to practice and that variations among normal children are so great that the results of single tests are unreliable. Park²¹ has used the method with adults but gives impressions rather than statistics. Jeghers²² calls attention to the prevalence and the importance of night blindness in drivers of automobiles. He has also reviewed^{22b} the literature on night blindness as a criterion of vitamin A deficiency and has added^{22c} observations on adults, using the method of Jeans.

Edmund and Clemmesen²³ have used as a criterion for loss of visual acuity in dim light the power of distinguishing simple geometric forms. Friderichsen and Edmund²⁴ use for their criterion the faintest illumination to which a child reacts when his eye is fully adapted to darkness. The investigator observes reflex movements—squeezing together of the lids, oculomotor

movements, turning the head toward the light. The authors make the surprising statements that improvement in visual acuity may occur within half an hour after the administration of halibut liver oil and that in some cases in which improvement has not occurred after administration of cod liver oil or halibut liver oil prompt improvement occurs after the administration of a preparation of spinach. Their method does not determine the rate at which visual purple is regenerated in light or in darkness as does that of Jeans, but it has the advantage that it can be applied to infants.

It is evident that the use of the methods described requires a certain amount of practice. Since they apparently reveal an incidence of night blindness far greater than any one had supposed might exist, confirmation of the conclusions of the various authors is needed. The retina obtains its vitamin A from the blood. It is known that vitamin A may disappear from the blood during starvation and during infections, even though considerable stores may remain in the liver.²⁵ Consequently, further observations are necessary in order to establish the value of tests of adaptation in dim light as a criterion of the reserves of vitamin A in the body.

Xerophthalmia and Keratomalacia.—These are symptoms of severe deficiency of vitamin A. Xerophthalmia, or dryness of the conjunctivae, is associated with atrophy of the para-ocular glands, with metaplasia of the epithelium of the glands and conjunctivae, and with loss of sensation in the conjunctiva, especially affecting the cornea. At first the dryness may be overlooked and may be associated with photophobia.²⁶ Triangular white spots—Bitot's spots—appear in the palpebral fissure; irregular wrinkled patches of xerosis are found over the bulbar conjunctivae and later over the cornea. A characteristic light brown pigmentation develops in the conjunctiva.²⁶ The superficial layers of the cornea degenerate. In the final stage, corneal softening, or keratomalacia, develops; severe impairment of vision results and permanent blindness is likely to follow.²⁷

Xerophthalmia is rare in the United States. A few clinical and pathologic studies have been published.²⁸ The disease may appear in epidemic form during periods of famine or in persons receiving a deficient diet for some other reason. It has been observed in prisoners, slaves and workmen.²⁹ A very remarkable epidemic occurred during the World War in Denmark

as a result of extensive exportation of dairy products and of the use of cheaper fats lacking in vitamin A for food.³⁰

The Treatment of Night Blindness Due to Vitamin A Deficiency.—Patients with normal power to absorb carotene and vitamin A may be treated by diet alone; the diet should include liberal amounts of milk, butter and green vegetables; cod liver oil or some other preparation of vitamin A or of carotene also should be administered. An improvement in dark adaptation may be demonstrable in a few minutes or hours after the ingestion of highly potent fish liver oils.³¹ Jeghers³² reports that visual acuity was restored within two or three weeks in adults with night blindness who received a daily dose of carotene equivalent to 10,000 units of vitamin A. In certain rare cases, gastro-intestinal disease may result in faulty absorption, as in the patient of Wilbur and Eusterman,³¹ whose diet had been adequate but who recovered from night blindness only after repair of a gastro-colic fistula.

SKIN

Dryness and scaliness of the skin, with a tendency to infection, were described in cases of xerophthalmia by Pillat.³² Characteristic lesions of the human skin due to vitamin A deficiency were first recognized as such by Frazer and Ch'uan-K'uei³³ in Chinese soldiers. Later reports confirm their results and add a few facts.³⁴ The lesions usually occur in sexually mature persons between 16 and 30 years of age and not in infants. They are much more frequent in men than in women. Ninety per cent of the patients have obvious ocular manifestations of vitamin A deficiency. The lesions appear first on the anterolateral surface of the thighs and posterolateral portion of the upper forearms and later spread to adjacent areas of the skin. They consist of pigmented papules, up to 5 mm. in diameter, at the site of the hair follicles, from which project keratotic plugs. In about one third of the cases, pustules develop. The skin is not oily and does not sweat. Microscopic section shows atrophy of the pilosebaceous glands with metaplasia and hyperkeratinization of the epithelium. Secondary infection may occur but hemorrhage does not. The treatment consists of a diet including butter, eggs, liver and cod liver oil (as much as 30 cc. a day). The first sign of improvement is a return of moisture to the skin. The keratotic papules heal slowly after a few weeks.

GASTRO-INTESTINAL TRACT

The Absorption of Vitamin A and of Carotene.—Drummond, Bell and Palmer³⁵ studied the absorption of vitamin A and carotene in a patient with a fistula of the thoracic duct opening into the pleural cavity.

Analysis of the fluid from the chest, made after the administration of vitamin A or of carotene by mouth, showed that very little of the carotene had passed into the chylous fluid, whereas nearly all of the vitamin A could be recovered. The vitamin A of natural oils and fats occurs as an ester; in preparations made by saponification it occurs as a free alcohol. When the vitamin was administered as the free alcohol, it was found in the lymph mainly in the esterified condition. It therefore appears that the mechanism of absorption of vitamin A includes linkage with fatty acids, probably in the intestinal wall. Such linkage is impossible in the case of the hydrocarbon carotene, a fact that may explain its lower coefficient of absorption. There is evidently always some loss of vitamin A or of carotene in the stools; in diets low in vitamin A, a negative balance may be demonstrated.³⁶ Nothing is known about the degree of destruction of vitamin A or of carotene in the gastro-intestinal tract under normal or pathologic conditions. If liquid petrolatum is administered with the vitamin, considerable loss occurs.³⁷ The loss is not so great if the oil is administered separately, and the effect is much greater in the case of carotene than in the case of vitamin A itself.

Exclusion of bile from the alimentary tract interferes with absorption of carotene and possibly of vitamin A. Altschule³⁸ found microscopic evidence of vitamin A deficiency in six of eleven infants dying of congenital atresia of the bile ducts. In rats in which a fistula had been made between the gallbladder and the colon and which had been fed diets free of vitamin A, Greaves and Schmidt³⁹ found that carotene was not absorbed. If glycodeoxycholic acid or deoxycholic acid was administered with the carotene, it was absorbed. Vitamin A, as such, was however absorbed by the rat with the internal bile fistula.

During infections, both carotene and vitamin A are poorly absorbed.⁴⁰

Patients with steatorrhea absorb vitamin A poorly.⁴¹

The faulty absorption of carotene from the gastro-intestinal tract—and in some cases, of vitamin A—under the conditions just discussed explains the occurrence of symptoms of vitamin A deficiency in persons consuming adequate diets, and the occasional failure of therapy with vitamin A or carotene when given by mouth. In certain rare cases, it may be advisable to administer vitamin A or carotene by injection, as in a case observed by Bloch.⁴²

Vitamin A in the Treatment of Gastro-Intestinal Disorders.—Manville⁴³ stated that the secretion of gastric mucus was decreased in rats fed diets deficient in vitamin A but that the secretion of acid was not impaired. The p_H of the gastric contents fell from normal values of 3.4 to 3.0-2.5 during avitaminosis. Gastric ulcers were found in from 60 to 100 per cent of the rats. The feeding of Fogelson's mucin did not relieve the ordinary symptoms of avitaminosis but tended to cure the ulcers. In a later paper Manville⁴⁴ found that the number of mucus-secreting elements of the intestinal tract decreased, exposing the mucous membrane to injury from solid components of the food and feces. Occult blood in the stools was the earliest evidence of deficiency of vitamin A. Olcott⁴⁵ was unable to find ulceration of the gastro-intestinal tract in avitaminosis A.

Boller⁴⁶ has treated cases of hypo-acidity and of gastric and of duodenal ulcer with vitamin A, stating that increase in gastric acidity resulted and that symptoms and signs of ulcer diminished.

Obviously, the experimental basis for the use of vitamin A in gastro-intestinal disorders is not yet clearly established.

THYROID

In 1926 Abelin⁴⁷ observed that the toxic effects due to feeding thyroid gland to rats could be lessened by diets rich in cod liver oil or in egg yolk. He later published extensive studies⁴⁸ showing the beneficial effects of diets high in protein, fats and bone marrow, provided cod liver oil, egg yolk and dried powdered vegetables also were included in the diets. His purpose was to devise a diet for the treatment of hyperthyroidisms in man; he did not direct his studies to the discovery of any one particularly beneficial constituent. That step was taken by von Euler and Klusmann.⁴⁹ In their experiments, rats were fed diets in which the only source of vitamin A was known amounts of carotene. The loss in weight of the animals due to daily injections of thyroxine could be prevented by the administration of carotene. In the following year Abelin⁵⁰ showed that injections of thyroxine decrease the stores of carotene and vitamin A in the liver of guinea pigs consuming a diet very low in carotene and receiving intraperitoneal injections of colloidal carotene. According to Eufinger and Gottlieb,⁵¹ the metamorphosis of tadpoles treated with thyroxine may be delayed by the administration of human plasma or of vitamin A. Fasold and Peters⁵² repeated the experi-

ments of von Euler and Klusmann and of Abelin, using a concentrate of fish liver oil ("Vogan"⁵³) as the source of vitamin A instead of carotene. The dose was so large (1 cc., or 40,000 units of vitamin A daily) that symptoms of hypervitaminosis were produced. These symptoms could be prevented by administration of thyroxine and could be cured, if paralysis had not developed. These authors demonstrated that thyroxine does not prevent the conversion of carotene to vitamin A in the rat and that the beneficial results in hypervitaminosis are due to the rapid destruction of the vitamin. There is in fact evidence that the conversion of carotene to vitamin A may be deficient in hypothyroidism. The milk of goats consuming their normal diet is pure white; after thyroidectomy the milk becomes yellow. Fasold and Heidemann⁵⁴ showed that the yellow color of such milk is due to carotene and that vitamin A is no longer present in it. The liver of guinea pigs after thyroidectomy contains carotene but no vitamin A.⁵⁵ Wendt⁵⁶ reported that the blood plasma of persons with cretinism contains little vitamin A; after oral administration of carotene there is little rise in the vitamin A of the plasma. This, according to Wendt, is due to a failure of conversion of carotene to vitamin A in cretinism. In hyperthyroidism low values of vitamin A are also found; in this case, because of rapid destruction of vitamin A. After successful treatment with iodine or by surgery, the values increase. After a large dose of vitamin A, the rise in plasma vitamin A is less marked and is more transient than in normal persons.

The evidence just presented appears to indicate that an antagonism exists between the action of thyroxine and that of vitamin A. It must be pointed out, however, that relatively large doses of both substances were used; also that few animals were used in some of the experiments. It seems reasonable to conclude that vitamin A may be more rapidly destroyed by an organism in which the metabolic rate is increased from any cause, including hyperthyroidism. But it is not so easy to understand how vitamin A can decrease the activity of thyroxine. A few observations have been published to show that thyroxine is destroyed in vitro by carotene.

Treatment of Adolescent Goiter with Vitamin A.—Fasold⁵⁷ administered "Vogan" (30 drops, three times a day) to seven girls with adolescent goiter; none had signs of hypothyroidism or hyperthyroidism. After three or four weeks the struma in each case had regressed to a remarkable degree, but several weeks after the drug was discontinued the struma recurred. The effect cannot necessarily be ascribed to vitamin A, for "Vogan" in the dose mentioned would furnish about 3.6 micrograms of iodine a day.⁵⁸

Treatment of Hyperthyroidism with Vitamin A.—Wendt⁵⁹ states that after large daily doses of "Vogan" (30 drops, three times a day, the total, 90 drops, contains about 3.6 micrograms of iodine and 145,000 "biologic units" vitamin A) three patients gained weight

and their basal metabolic rate returned nearly to normal; two other patients improved. Dietrich⁵⁹ noted improvement in three of six patients (apparently permanent improvement in two) and none in two. The improvement required weeks. Abelin⁶⁰ regards the use of vitamin A as an aid in the treatment with iodine and with diiodotyrosine, stating that it greatly lessens the crises and the temporary exacerbations that are liable to occur with these forms of medication. Obviously, no conclusions as to the value of vitamin A in this disease are justified until more cases are reported and until the reports deal more critically with the other factors which may bring about improvement, especially the factors associated with the other constituents of the preparations used, with rest and with improved mental outlook.

URINARY SYSTEM

Urinary Lithiasis.—The assertion that diets deficient in vitamin A may cause urinary calculus and that the administration of vitamin A together with an acid ash diet may aid in the solution of urinary calculi has been recently reviewed by the Council on Pharmacy and Chemistry.⁶¹ The Council concludes that there is no doubt that urinary stone may be produced in experimental animals by diets deficient in vitamins A and D and unbalanced in mineral content.⁶² But the majority of investigators fail to find that a deficiency of vitamin A alone will cause stone. Higgins⁶³ is the chief proponent of the claim for the specific effect of lack of vitamin A in the production of urinary stone in man and of its solution by acid ash diets and vitamin A. Kayser, who discussed the paper of Higgins, pointed out that lithiasis, when it does occur in the rat with avitaminosis, is a very late manifestation. Children with deficiency of vitamin A rarely have calculi. In human beings with calculi, epithelial keratinization, the specific lesion of avitaminosis A, is lacking. In a large series of cases of stone, Kayser has failed to find evidence of dietary deficiency in a single case. Many of his patients had had diets rich in milk and eggs. In his experimental and clinical work, Higgins did not try separately the effects of administering vitamin A and acid-producing salts. Since the report was published, Oppenheimer and Pollack⁶⁴ have treated a series of cases of urinary stone with diets rich in vitamins A, B, D, E and G and having an acid ash, administering sufficient ammonium chloride to assure an acid reaction in the urine (p_H below 5.2). Fifty-two patients with stone were studied; twenty-seven were observed for from six to sixteen months (on the average eleven months). In two, uremia and acidosis seemed to have been precipitated by the regimen. In none of the subjects was even partial solution of the calculi demonstrable by x-ray examination; in five, the size of the stone increased and in one, a new stone formed during the treatment.

It may be concluded that, although urinary calculi may be produced in experimental animals by feeding

53. "Vogan" is a concentrate of fish liver oils; 1 cc. contains 40,000 rat units of vitamin A, an unstated amount of vitamin D, and about 6 micrograms of iodine.

special diets, the factors involved are not yet clearly defined. Further study is required before the results can be applied to man. The view that diets deficient in vitamin A cause urinary lithiasis in man is not supported by the clinical evidence.

REPRODUCTIVE SYSTEM

In the Male.—It has been shown that the testes of rats degenerate in the course of deficiency of vitamin A. Evans⁶⁵ has demonstrated that males eating a diet free of vitamin A but adequate in vitamin E become sterile in three months, whereas those receiving adequate vitamin A but no vitamin E do not become sterile until later. The effects of moderate deficiency of vitamin A on fertility in man are unknown, nor is anything known about the relative importance of moderate deficiency in men and in women.

In the Female.—The vaginal mucous membrane becomes permanently cornified in animals deprived of vitamin A. Observation of the vaginal smear may be used as a method of detecting vitamin A deficiency.⁶⁶ In castrated female rats in which vitamin A deficiency has been produced, injections of the principle from human placenta fail to cause the appearance of mucoid cells in the vagina;⁶⁷ and in castrated female mice with diets deficient in carotene and vitamin A, estrus can be produced by injections of estrogen together with the administration of carotene, but not by estrogen or by the carotene alone.⁶⁸ In uncastrated rats, Mason and Ellison,⁶⁹ by the use of the lavage method of obtaining smears stained supravitaly with neutral red, have been able to demonstrate the presence of estrous cycles even in A-deficient animals in which abnormal cornification has become too severe to permit of their identification by dry stained smears. In castrated animals, small numbers of cornified cells continue to appear even after vitamin A therapy. It is therefore evident that the influence of deficiency of vitamin A on the estrous cycle is not only directly on the vaginal mucous membrane but on or through the ovary also. The effect on the hypophysis is as yet unknown. The influence of excessive doses of vitamin A (as carotene) on the sexual functions of female rats has been studied by Sherwood, Brend and Roper.⁷⁰ In rats receiving a daily dose of carotene equivalent to from 1,500 to 3,750 international units of vitamin A per day, the vaginal smears did not progress from the stage of nucleated epithelium to that of cornified cells. Normal estrous cycles did not return for twenty days after the feeding of the carotene had been discontinued. During the period of ingestion of the carotene, the rats showed no desire to copulate.

In Human Subjects.—Simpson and Mason⁷¹ report that the administration of cod liver oil or of halibut liver oil relieved symptoms and pathologic signs in

thirty cases of senile vaginitis. Fasold⁵⁷ administered a concentrate of fish liver oil ("Vogan"; 30 drops, three times a day = 145,000 international units of vitamin A) to seven adolescent girls with large goiters of puberty. In four of the girls the menses ceased for the period of seven months during which vitamin A was administered and were resumed from four to six weeks after the treatment was discontinued. Menstrual disturbances that had been complained of before the treatment did not reappear.

THE BLOOD AND BLOOD FORMING ORGANS

Anemia and Vitamin A Deficiency.—French authors⁷² report that regeneration of hemoglobin and red cells in the anemia induced in dogs by repeated bleedings is facilitated by the administration of carotene. This work lacks confirmation. In seven patients among thirty-five with keratomalacia, Pillat and Yang⁷³ found an anemia which they believe could be explained only as a result of deficiency of vitamin A and which was cured rapidly with cod liver oil. The belief that pernicious anemia is associated with deficiency of vitamin A in the diet has now been discredited. It seems clear that anemia is not a regular symptom of deficiency of vitamin A, and the use of vitamin A for the treatment of the anemias does not rest on a secure foundation.

The Thrombocytes and Vitamin A.—The assertion of Cramer, Drew and Mottram⁷⁴ that the number of thrombocytes is diminished in avitaminosis A seems to have been disproved by Bedson and Zilva,⁷⁵ who used more accurate methods of counting the blood platelets, and by Falconer and Peachey.⁷⁶ Their control animals, however, received a perfectly normal diet and not the basal diet plus vitamin A. Lorenz⁷⁷ believed that "Vogan," a concentrate of fish liver oil, enables the body to "regulate" the number of thrombocytes. In children and in guinea pigs he observed that, following the administration of the drug, originally low platelet counts rose, originally high counts fell. He attributes this effect to vitamin A. Schiff and Hirschberger⁷⁸ at first agreed but later stated that the solvent in "Vogan," sesame oil, contains a hitherto undescribed substance which they designate as vitamin T, which causes a rise in blood platelets.

The Granulocytes and Vitamin A.—Crimm and Short⁷⁹ state that the earliest manifestation of cellular changes associated with vitamin A deficiency in dogs and rats is a "neutrophil index lag"; large doses of vitamin A administered to normal animals or to normal

persons (70,000 international units daily) cause a shift to the left in the neutrophilic index. This shift is not due to vitamin D. It would seem evident from this work that the lag is not marked enough to be of value in the diagnosis of avitaminosis; the shift to the left requires large amounts of vitamin A administered over a long period and is not present in active infections, possibly because a shift has already occurred.

It may be concluded that no very striking effect of vitamin A on the cellular elements of the blood has been discovered.

VITAMIN A AND THE NERVOUS SYSTEM

Edward Mellanby⁸⁰ stated that, when diets containing a large amount of cereal (other than yellow maize) and deficient in vitamin A are eaten by young puppies, degenerative changes occur in the spinal cord; demyelination can be demonstrated by the Marchi stain. The presence of any source of vitamin A in the diet (cod liver oil, butter or carotene) prevents or diminishes this change. He believed that the nervous symptoms in convulsive ergotism, pellagra, lathyrism, the subacute combined degeneration in pernicious anemia, tabes dorsalis and multiple sclerosis may be related to deficiency of vitamin A. In 1935 Mellanby⁸¹ reported demyelination, chiefly of the peripheral nervous system, in growing rabbits consuming a diet poor in vitamin A and reiterated his belief that diets high in cereal aggravate the condition. Later he ascribed the metaplasia of specific epithelium to lesions of the trophic nerve fibers due to deficiency of vitamin A.

Using adult dogs, Suzman, Muller and Ungley⁸² were unable to produce lesions in the nervous system or abnormal nervous symptoms as a result of the ingestion of diets free of vitamin A and containing an excess of cereal. Their animals, at least toward the end of the experiment, had exhausted their stores of vitamin A. In a certain number of rats, but not in all, consuming diets deficient in vitamin A, Zimmerman⁸³ and Zimmerman and Cowgill⁸⁴ were able to observe incoordination and muscular weakness. In these rats only they observed degeneration of the spinal cord and of the peripheral nerves. The diets contained no cereal but contained an adequate amount of unsaturated fatty acids. Sutton, Setterfield and Krauss⁸⁵ were able to demonstrate in frozen sections with polarized light myelin degeneration of the peripheral nerves in rats receiving a diet deficient in vitamin A. The degeneration occurred at about the same time as did xerophthalmia. Aberle⁸⁶ found that the appearance of nervous symptoms was always later than the continuous appearance of cornified vaginal cells.

Bartz and Schmitt⁸⁷ were able to demonstrate by satisfactory methods the presence of relatively large

amounts of carotene and of vitamin A in the peripheral nerves of frogs and to show that starvation depletes the supply whereas feeding with carotene restores both the carotene and the vitamin A content.

More knowledge is obviously required as to (a) the function of vitamin A in the nervous system, (b) the other deficiencies in the diets used, (c) the influence of the age of the subject, and (d) the possible specific effects of cereals, before any intelligent application can be made of this experimental work to the treatment of nervous disorders in man.

TUMORS

The incorrect assumption that vitamin A is the "growth vitamin" has led several investigators to study the effect of vitamin A on the growth of tumors. The conflicting results were summarized by Baker.⁸⁸ She was able to show that highly purified vitamin A—but not carotene—in suitable concentration stimulates the growth of fibroblasts in tissue culture; higher concentrations are distinctly toxic. Kuh⁸⁹ reported that the amount of vitamin A present in the usual diet has no effect on the growth of transplanted tumors in mice but that large doses of carotene inhibit the growth of such tumors, provided the animal can convert the carotene to vitamin A. The effective dose on the basis of weight would be equivalent to 0.6 Gm. of carotene, i. e., 1,000,000 international units daily for a person weighing 60 Kg. Dittmar⁹⁰ reports that large doses of vitamin A decrease the percentage of successful tumor implants in mice. As the doses were from 1,000 to 2,000 rat units daily, it seems possible that he may have been dealing with a toxic effect due either to the vitamin itself or to some other substance in the concentrate. Lustig and Wachtel⁹¹ believe that local applications of concentrates of vitamin A assist in the healing of malignant ulcers, provided radium also is used. The influence of vitamin A deficiency on the growth of tumors has been little studied, because complete deficiency is likely to be fatal before the growth of the tumors can be accurately observed. Wolbach and Howe⁹² state their belief that in man defective formation of the enamel of the teeth, denticles, pulp bone and cemento-exostoses may reasonably be regarded as possibly due to vitamin A deficiency. Orten, Burn and Smith⁹³ produced moderate deficiency of vitamin A in rats by feeding the animals on a diet deficient in the vitamin from weaning until signs of deficiency developed, then supplementing the diet with from 0.7 to 6 international units of vitamin A daily. In those rats which survived for a year, they found quite constantly large painless odontomas of the maxillae developing from the embryonic cells of the pulp.

liver oil or concentrates has been enthusiastically advocated by Löhr.⁹⁴ He ascribed his apparently successful results in part to a bactericidal influence of the preparations used, in part to a stimulation of growth of epithelium. He presented illustrative cases but no controlled observations. He later⁹⁵ described the treatment of acute and chronic osteomyelitis by means of local applications of cod liver oil ointment and plaster bandages.

Andernach and Löhr⁹⁶ advocate the injection of cod liver oil into the joint spaces in chronic arthritis of various types; a rather severe (sterile?) inflammation ensues, following which improvement occurs, probably as a result of hyperemia. Their cases, however, are not analyzed from a statistical standpoint. Several other authors have reported good results from the use of local applications of ointments containing vitamins A and D.⁹⁷ Solutions of carotene in oil have been recommended by Rachet and Busson⁹⁸ for the local treatment of ulcerative colitis. The work was not controlled by the use of oil without carotene. Balachowski⁹⁹ used colloidal carotene in salt solution for the local treatment of superficial lesions of the eye, gingivitis, chilblains, fissures and inflammations. As he states that the treatment was just as effective after the solutions had become bleached, it is not possible to attribute his results to the action of carotene.

The clinical work just reviewed seems to have been done without a preliminary experimental study of the possible factors involved. The experimental work done by other investigators throws doubt on any specific action of the vitamins contained in the preparations applied locally. Lauber and Rocholl¹⁰⁰ find that the base of the ointment used is effective. Lundh¹⁰¹ studied the healing of wounds produced in guinea pigs, treating the wounds on one side with various ointments and permitting the wound on the other side to heal without an ointment. Cod liver oil did not promote healing; the wounds treated with yellow petrolatum healed more slowly than the wounds exposed to dry air; the wounds treated by an ointment containing 10 per cent zinc oxide or 10 per cent zinc oxide and 1 per cent halibut liver oil healed in twenty-five days. Those treated with an ointment containing 10 per cent or 25 per cent halibut liver oil healed in twenty-three days. As he gives only the average time of healing and not the times of healing for the individual animals, it is not possible to accept his conclusion that the difference is significant, much less that it is a specific effect. Finally, the differences are so small that they by no means justify the enthusiasm of the clinical reports.

VITAMIN A AND INFECTIONS

Severe spontaneous infections in animals with xerophthalmia were first reported by McCollum.¹⁰² Such infections cannot be prevented by vitamin D but can be prevented by the administration of cod liver oil or of carotene in amounts sufficient to prevent the development of symptoms of deficiency of vitamin A.¹⁰³ Animals suffering from deficiency of vitamin A are more susceptible than control animals to a variety of infections artificially produced either by inoculation through the mouth or by intraperitoneal injection of cultures.¹⁰⁴ The loss of resistance may appear even before other symptoms of vitamin A deficiency,¹⁰⁵ and it may appear in animals receiving a diet considered nearly adequate, as in the experimental epidemics in mice studied by Webster and Pritchett¹⁰⁶ and by Pritchett.¹⁰⁷ The study of experimental epidemics, of obvious importance for infections in man, has demonstrated the possibility that moderate degrees of deficiency may lower resistance but that many more factors are involved than deficiency of vitamin A.¹⁰⁸

The mechanism of lowered resistance to infection in vitamin A deficiency is not understood. Although poor general condition plays a role,¹⁰⁹ infection seems more likely to occur in animals suffering from a deficiency of vitamin A than in those with a deficiency of other vitamins. The characteristic lesion in animals with fully developed vitamin A deficiency is degeneration of specialized epithelium which is replaced by keratinizing epithelium. In the case of the respiratory tract, alterations of the mucous membranes are undoubtedly the chief cause of spontaneous infections. In case of infections following inoculation into the blood stream or peritoneal cavity, and in case of loss of resistance in moderate deficiency of vitamin A, some other mechanism must be involved. The majority of writers agree that both the normal antibodies of the serum and the power to produce antibodies are not affected by dietary

deficiencies excepting in the terminal stages and that deficient animals are not more susceptible than controls to bacterial toxins.¹¹⁰ The defensive response of the tissues in vitamin deficiency has not been adequately studied.

Resistance to infection in man may be decreased in cases with marked deficiency of vitamin A. Bloch¹¹¹ reported that children suffering with xerophthalmia are liable to severe infections and that, even after recovery from the deficiency, their liability to death from infection remains high for years.¹¹² The majority of observers agree with Bloch's conclusions that infections are frequent and severe in cases of xerophthalmia, but Spence¹¹³ failed to observe this. Moderate degrees of vitamin A deficiency have been assumed to lower resistance to infection in man. Four methods have been used to show that vitamin A deficiency might exist in the group subject to infection and not in the control group: (1) calculation of the intake of vitamin A in the two groups, (2) analysis of the liver for vitamin A in persons dying of infection and in those dying from accident, (3) analysis of the blood for carotene and for vitamin A, and (4) the demonstration of night blindness in the group subject to severe infection. The first method is essentially that of Barenberg and Lewis,¹¹⁴ of Hess, Lewis and Barenberg¹¹⁵ and of Wright, Frosst, Richel and Lawrence.¹¹⁶ They were unable to lessen the incidence or the severity of respiratory infection in groups of infants by administering cod liver oil, halibut liver oil or carotene. However, the infants in their control group were already receiving adequate amounts of vitamin A. It is also possible that an inadequate diet at an age earlier than that of their subjects may be of importance.¹¹⁷ Analyses of the liver have been carried out by several authors,¹¹⁸ who agree that low values are usual in the livers of persons dying of infections. But it must be emphasized that the stores of vitamin A are depleted during periods of underfeeding and by infection itself. Analyses of the blood for carotene and for vitamin A¹¹⁹ also show a decrease during infection. In children subject to repeated respiratory infections, but not recently ill, the average level of blood carotene is lower than in other children. But the increased liability to infection which could be ascribed to low blood carotene is only about 10 per cent.¹²⁰ The recent rather intensive study of

night blindness has afforded a more direct method of ascertaining the presence of moderate degrees of vitamin A deficiency. Jeghers¹²¹ in a group of 162 medical students found fifty, or 36 per cent, whose visual adaptation to dim light was subnormal and fifty whom he regarded as certainly normal. The calculated daily intake of vitamin A in the subnormal group was 2,445 international units; in the normal group it was 5,500. The incidence of colds during the preceding year was nearly equal (2.2 per person vs. 2.1), but the duration was 7.4 days in the subnormal group and 5.4 days in the normal group. It is obvious that the differences are not very great and certainly do not justify terming vitamin A "the anti-infective vitamin." More studies of this type are essential.

Within the past few years, several authors have studied the effect of administering vitamin A on the incidence or on the course of infections. In these studies, no attempt was made to ascertain the presence or the absence of vitamin A deficiency. A favorable effect from administration of vitamin A has been claimed on the outcome in pneumonia by Donaldson and Tasker¹²² and in measles by Ellison.¹²³ In studies which seem to have been better controlled, no favorable effect was found in pneumonia by Orenstein,¹²⁴ in measles by Mackay and her co-workers,¹²⁵ in the complications of scarlet fever by Sutliff and his co-workers,¹²⁶ or by Clausen,¹²⁷ and in pertussis by Sehestedt.¹²⁸ It was shown that the vitamin was absorbed.¹²⁷ The literature on the effect of the administration of vitamin A on the prophylaxis of illness, especially of colds, is also conflicting. Most of the reports state that the severity of colds is less in the group receiving vitamin A. Some of the reports state that the incidence of colds is also less.¹²⁹ Although the investigators attempted to secure adequate controls, it was usual to select volunteers for the experimental groups. The stated incidence of colds during a previous year was often compared with the observed incidence during the experiment. The subjective element was not always eliminated. In Cameron's study¹³⁰ this factor was recognized and her control subjects received

a placebo of lactose. Cameron also calculated the daily intake of vitamin A. She found that, although the incidence of colds was not decreased by adding 5,000 international units of vitamin A to a diet already containing 4,300 units, the duration was decreased. The general criticisms just raised to this type of study have been met in the report of Shibley and Spies.¹³¹ These authors studied groups of students selected by random sampling; no subject knew to which group he belonged; the record of infections was accurate. One group received 200,000 international units of vitamin A and 4,000 units of vitamin D per week; another received, as viosterol, 400 units of vitamin D, and the third received maize oil. The seasonal incidence of colds and their severity were alike in all groups. The duration of colds was significantly shorter in those students who received vitamin A.

The evidence reviewed indicates that severe deficiency of vitamin A lowers resistance to infection in man and that the administration of vitamin A during the course of an infection probably has no beneficial effect on the outcome unless severe deficiency is present. There is evidence that moderate deficiency of vitamin A may also increase the duration or severity of respiratory infections in man; that an adequate intake of vitamin A may lessen the severity and duration of infection in persons moderately deficient. It is also evident that many other factors are of equal or greater influence on infection, and no justification exists for calling vitamin A "the anti-infective vitamin."

HYPERVITAMINOSIS: INJURIOUS EFFECTS ASCRIBED TO PREPARATIONS OF VITAMIN A

When large amounts of pure carotene in a suitable solvent are administered to animals by mouth or by injection, no harmful effects are observed,¹³² although Lewis and Reti observed that the impure lipid soluble extract of carrots is toxic. In human beings following the ingestion of large amounts of vegetables containing carotene, and also in persons suffering from certain metabolic disorders, especially diabetes, carotene may accumulate in the skin in amounts sufficient to cause a deep yellow color known as xanthosis cutis. The term "carotenemia," although frequently applied to this condition, is not an appropriate designation, for carotenoid pigments are usually present in the plasma of human blood, and in lipid nephrosis a marked increase of the plasma carotene may exist¹³³ without xanthosis cutis. No harmful effects have been ascribed to hypercarotenemia, but xanthosis cutis may be mistaken for jaundice.

When large amounts of concentrated preparations of vitamin A are administered to certain animals, injurious effects are observed. It is likely that some of these effects are due to vitamin A, but satisfactory proof is lacking because pure preparations of vitamin A were not used. It has been shown that the injurious effects do not occur if the vitamin is destroyed in the preparations by oxidation or by ultraviolet irradiation. This argument is not convincing because these procedures may destroy some other toxic substance.

Drigalski¹³⁴ administered 0.5 and 1 cc. daily of a concentrate of fish liver oil ("Vogan"; 1 cc. = 40,000

rat units of vitamin A) to rats weighing 100 Gm. Their coats became rough; cachexia, catarrhal conjunctivitis, hemorrhagic rhinitis and diarrhea developed. Death occurred within five to eight days in the animals receiving the larger dose and within seven to nineteen days in those receiving the smaller dose. At autopsy Drigalski and Laubmann¹³⁵ found degeneration of the renal glomeruli and tubules, proliferation of the reticulo-endothelial cells of the spleen, absence of striations in some of the cardiac muscle fibers, degeneration of the testes, and only slight changes in the liver. Moll, Domagk and Laquer¹³⁶ report similar injuries in mice, and Fasold¹³⁷ calls attention to an elective fatty infiltration in the Kupffer cells of the liver. Collazo and Rodriguez¹³⁸ add to the symptoms exophthalmos and spontaneous fractures. The lesions of the bones suggested osteomalacia¹³⁹ but could not be prevented by large doses of vitamin D. Rossi¹⁴⁰ doubted the existence of "hypervitaminosis A"; but the dose of vitamin used by him was about 400 units a day for the rat, whereas the other investigators had used from 20,000 to 40,000 units a day.

The literature which deals with injurious effects following the use of cod liver oil or of relatively small amounts of concentrates is very difficult to evaluate. Hopkins¹⁴¹ found that an excess of cod liver oil in the diet of rats was injurious unless "balanced" by the addition of vitamin B complex. Following this observation, the theory of vitamin balance has developed,¹⁴² but while accepting the observations as accurate, it is obvious that one must consider not only the relative amounts of vitamins but also the relative amounts of minerals and of other substances. As a rule the basic diets have been artificial ones, unusual for the species of animals being studied. Swedish workers report that cod liver oil, even in such small doses as 0.1 cc. per kilogram daily, may cause a variety of injurious effects, especially on the heart muscle, in mice, rats, rabbits, dogs, calves, cats, pigs, and human infants.¹⁴³ Norris and Church¹⁴⁴ have stated that the symptoms resemble those due to deficiency of vitamin B complex and may be due to isoamylamine in the small

amount found in cod liver oil, but they failed to test their oil for the presence of this substance. Their view is not supported by the direct experiments of Bell, Gregory and Drummond,¹⁴⁵ who showed that a disturbance of growth in rats was produced by a diet containing 15 per cent of cod liver oil and could be made to disappear by an increase in the amount of vitamin B complex. The toxic substance in their cod liver oil could be extracted with hydrochloric acid but was not an amine. Turner, Meigs and Converse¹⁴⁶ stated that rabbits fed a grain mixture with low grade roughage have an even chance of surviving to an age of 180 days. If 0.7 Gm. of cod liver oil per kilogram is added, death will almost certainly occur between 90 and 150 days of age. If the roughage is of good quality alfalfa hay, little if any injury is produced by cod liver oil. On the other hand, calves receiving the grain mixture, poor quality roughage and skim milk do not survive unless cod liver oil (up to 0.7 Gm. per kilogram) is supplied but are injured by 2 Gm. per kilogram. Madsen and his co-workers¹⁴⁷ developed a synthetic diet containing cod liver oil but no hay or grain on which sheep and goats could be reared although the goats did not thrive. Rabbits and guinea pigs fed this diet did not survive. A constant symptom of failure to survive was paralysis due to degeneration of the skeletal muscles. The heart muscle was frequently involved. The substitution of a concentrate containing vitamins A and D for the cod liver oil delayed the onset and lessened the severity of the symptoms. The addition of cod liver oil (0.7 Gm. per kilogram daily) to a natural pasture diet caused death with the characteristic lesions in goats and sheep; but 0.1 Gm. of cod liver oil per kilogram daily caused no injury to animals on a normal diet. Cox and Roos¹⁴⁸ have repeated the experiments of Agduhr and Höjer. Although the rats in these experiments received doses of cod liver oil sixty times as large as the doses in Agduhr's experiments, Cox and Roos found no lesions in the heart. The whole question of degeneration of muscle and nervous tissue in animals consuming synthetic diets is at present the object of active study by several investigators. The questions of the presence of toxic substances and the absence of protective factors are involved. It appears at the present time that very little evidence exists that hypervitaminosis A is involved in the effect.

Occasional untoward effects have been ascribed to cod liver oil given to patients. Czerny¹⁴⁹ gave 80 cc. daily to tuberculous children and frequently observed the development of seborrheic dermatitis of the face and scalp. Sensitivity to cod liver oil, resulting in urticaria or eczema, has been reported in four patients by Balyeat and Bowen¹⁵⁰ and to halibut liver oil in two cases by Pfister.¹⁵¹

In view of the general favorable clinical experience with the use of cod liver oil, one would have to be very sure that the evidence for its harmful effect on human beings is strong enough to be accepted. The literature quoted in this section is so contradictory as to afford, at the present time, no adequate evidence.

Council on Pharmacy and Chemistry

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
PAUL NICHOLAS LEECH, Secretary.

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association held its annual meeting at the Association headquarters, Friday and Saturday, March 18 and 19, 1938. Those present were Drs. David Barr, J. Howard Brown, S. W. Clausen, H. N. Cole, C. W. Edmunds, Morris Fishbein, E. M. K. Geiling, Ernest E. Irons, Paul Nicholas Leech, G. W. McCoy, E. M. Nelson, W. W. Palmer, William C. Rose and Torald Sollmann.

The following were present either for certain discussions or during the entire meeting: Dr. James S. McLester and Dr. George R. Cowgill of the Council on Foods; Dr. Austin Hayden, Secretary of the Board of Trustees; Dr. Olin West, Secretary and General Manager of the American Medical Association, and Dr. Harold Smith, Chairman of the Council on Dental Therapeutics of the American Dental Association.

Dr. Torald Sollmann was reelected chairman of the Council and Dr. W. W. Palmer was reelected vice chairman.

Among the many items discussed, the following may be of interest both to physicians and to manufacturers:

Status of Permissible Claims for Vitamins.—At the close of 1937 the Council revised the chapter in New and Nonofficial Remedies in reference to the status of permissible claims for accepted vitamin preparations. The general consensus of the Council was that there existed little need for a change in these claims but that it would be well to refer certain questions to the Cooperative Committee on Vitamins in view of recent developments in the literature. The committee was asked to report back to the Council in the near future.

Vitamin Mixtures.—The Council took cognizance of the increasing tendency on the part of pharmaceutical houses to promote mixtures of vitamins, particularly in tablet and capsule forms. The subject was referred to the Cooperative Committee on Vitamins for study and report.

Nomenclature of Vitamins.—The Council voted that New and Nonofficial Remedies 1939 be edited with a view to promoting the use of the scientific or chemical names for vitamins as promptly as possible. Eventually the name "vitamin" will be eliminated, but it will be used as a synonym during the transition period until the chemical names become fairly well established.

Advertising Claims for Vitamin Preparations.—Some recent actions of the Federal Trade Commission in the consideration of claims made for certain vitamin preparations were considered. The decisions discussed were in harmony with the views of the Council. The spirit of the Council's requirements should be enforced in passing on advertising. In other words, if a firm makes a claim that a vitamin will be of value in some phase of disease, the claim should be accompanied by a modifying clause to the effect that it applies only when there has been an exhaustion of body reserves of the vitamin and ingestion of the particular vitamin is inadequate; that is, vitamins are indicated when the condition is due to lack of vitamins themselves.

Possibility of Reducing Number of Types of Vitamin A and D Preparations.—The Council has adopted a decision limiting the dosage claims for vitamin preparations, which states that the daily dosage shall provide at least as much vitamin A and vitamin D as is contained in a teaspoonful of cod liver oil of

minimum strength, and not more than 1,000 units of vitamin D and 10,000 units of vitamin A. In applying this decision to vitamin A and D preparations, it becomes obvious that there are more classes of vitamin A and D preparations than are really necessary and the multiplicity of dosage forms also imposes an undue burden on the physician. One of the Council's referees pointed out that the number of vitamin A and D preparations should be limited by restricting the number of concentrations in each form to be recognized by the Council. The Council voted that this matter be referred to the Cooperative Committee on Vitamins for consideration and report.

Vitamin E.—Recently the use of vitamin E in the form of wheat germ oil has been suggested for the treatment of habitual abortion in women. One of the referees reviewed for the Council in detail the available evidence. It was pointed out that evidence for the effectiveness of this treatment is meager and that it is the practically unanimous opinion of nutritionists that vitamin E is widely distributed in foods and that there is no reason normally to suspect a deficiency. In most cases the amount of wheat germ oil that would be administered would be but a small fraction of the vitamin E which would be consumed in the ordinary diet. The Council referred the referee's report to the Cooperative Committee on Vitamins with the request that it be published after consideration by the committee.

Advertising Brochures.—In the printed abstract of the minutes of the Council for 1937 (*THE JOURNAL*, May 29, 1937, p. 1887) appeared the following paragraph:

Brochures Issued by Pharmaceutical Houses.—There has recently been a tendency on the part of certain pharmaceutical firms to issue brochures advising the profession on the status of certain diseases and making recommendation for therapeutic treatment. In such brochures a certain drug is extolled, frequently to the exclusion of other therapeutic measures. The members of the Council felt that comprehensive reviews of medicine, surgery or the specialties are the function of duly qualified persons who undertake the task from altruistic motives rather than for the purpose of advocating the sale and use of particular commercial products. The members of the Council recognize the usefulness of educational brochures when prepared under proper auspices and with proper restrictions.

The general opinion of the Council was in confirmation of the foregoing statement. Members of the Council felt that teaching should be done by those persons especially qualified to do the work of teaching and that brochures are generally edited with the view of increasing the sale of the product. Therefore, the contents of brochures are frequently found to be definitely biased. The Council decided to prepare, with the aid of the editor of *THE JOURNAL*, a report dealing with this subject.

Liver Preparations.—It was announced that a number of commercial liver preparations have been considered by the U. S. P. Anti-Anemia Preparations Advisory Board for approval. The standards of this board and those of the Council are not the same. It was brought out that the U. S. P. Advisory Board has not published its standards. Furthermore, Council-accepted products must comply with other rules of the Council besides those dealing simply with potency. It was thought that the U. S. P. committee would probably publish its standards in the near future. A motion was adopted to the effect that the Council consider it highly desirable that both the U. S. P. Anti-Anemia Preparations Advisory Board and the Council on Pharmacy and Chemistry should arrive at common standards for liver preparations, with a view to their adoption and inclusion in New and Nonofficial Remedies.

Ergonovine.—In 1937 Eli Lilly and Company submitted to the Council a detailed and documented brief to substantiate the claim that the Council should recognize its proprietary name for the substance for which the Council had coined the nonproprietary name Ergonovine. This claim was made on the basis of the patent as evidence of prior discovery of the alkaloid. After careful consideration it was voted that the Council, so far as its rules are concerned, does not concur in the contention that Eli Lilly and Company has such prior right, either for Ergonovine or for its salts. [The Council does believe, however, that by virtue of its patent Eli Lilly and Company has a prior right to a proprietary name for a mixture of ergot alkaloids, such as is defined in the patents.]

The Pharmacopoeial Convention in 1940.—There was general discussion of the pharmacopoeial convention to be called for 1940, and a desire expressed that the objectionable features

of the convention of 1930 as it affected the medical profession should not be repeated. The Council voted to inform the Board of Trustees of the American Medical Association of its consideration of the 1940 convention of the U. S. Pharmacopeia with the suggestion that the medical profession do its utmost to insure adequate medical representation.

Status of Insulin and Insulin Preparations.—The Council considered the status of crystalline zinc insulin. The opinion was that the product zinc insulin crystals should be accepted for inclusion in New and Nonofficial Remedies, with the condition that acceptance of otherwise acceptable brands will not become official until the product is sold on the open market.

Aminophylline.—The Council published a statement on aminophylline (*THE JOURNAL*, June 26, 1937, p. 2203) restricting the recognizable claims for accepted products to their use as a diuretic and mild myocardial stimulant. In view of the evidence available at that time the Council reported that it could not recognize claims which would infer usefulness in overcoming the pain of angina pectoris. One of the manufacturers referred to some evidence published at about the time the Council issued its last report. The Council considered this paper but decided that for the present no alteration should be made in the decision on permissible claims for this drug. The Council, however, will scrutinize carefully any further evidence that may be published in the scientific literature to determine whether or not the permissible claims for aminophylline may be modified.

Barbituric Acid and Its Derivatives.—The Board of Trustees has requested the Council to issue a report on barbituric acid and its derivatives in view of the widespread abuses of these drugs. The Council decided to secure the cooperation of certain individuals to aid in the preparation of a report relative to the dangers of barbituric acid and its derivatives.

Antiseptics and Germicides.—The Council authorized a study and report which may aid in determining present-day scientific interpretation of such terms as "antiseptic," "germicide," "bactericide," "fungicide," "disinfectant."

Generic Names.—In view of the recent cellophane decision the Council is of the opinion that it is correct in coining new brief, usable, nonproprietary, generic names for products protected by patents, so that when a patent expires there will already be available and in use a suitable nonproprietary name. The Council was informed at that time, however, that the cellophane decision had not yet gone before the highest court.

Acquisition of Pharmaceutical Houses by Nostrum ("Patent Medicine") Interests.—For a number of years there have been holding concerns or groups of individuals who have had financial interest or control, or both, in patent medicine concerns and ethical proprietary houses. Of late there has been a further tendency of nostrum ("patent medicine") houses to purchase, or obtain financial control of, concerns which make products for the physician. The Council decided that it should be very watchful of companies acquired by nostrum interests or closely associated financially with nostrum interests. In those instances in which the Council has information that the best interests of either the public or the medical profession are being jeopardized by a house under such control and having Council accepted products, immediate action will be taken against the firms, particularly in relation to the application of rule 11. It was recommended that this action should be included in the published minutes of the Council, and that this would constitute a general notification to the pharmaceutical industry of the Council's policy.

Series of Articles on Glandular Therapy.—The book "Glandular Physiology and Therapy," which contained the series of articles published approximately two years ago, has been a success. Since the book was issued additional work has been done indicating that new chapters are needed and some now in the book should be modified or omitted. The Council decided to sponsor another series of articles on this subject with a view to publication some time in 1939.

Therapeutic Research.—The report of the Committee on Therapeutic Research was discussed in detail; the complete report will be found under Reports of Officers (*THE JOURNAL*, April 30, 1938, p. 1484).

Comparative Safety of Anesthetics.—The Council directed that a communication be sent to the Council on Scientific Assembly pointing out the desirability of keeping the subject of reports on the comparative safety of anesthetics actively before the clinical sections and emphasizing that the Council is desirous of receiving any reports of accidents following the use of anesthetics.

Drug Store Window Display Advertising.—The Council voted that pharmaceutical firms again be informed that window display advertising arranged by the manufacturers comes within the category of the Council's rules dealing with advertising; that manufacturers of Council accepted products must abide by the Council's rule of not using an accepted preparation, or preparations, to advertise a nonaccepted preparation, or preparations, and that the manufacturers will be held responsible when such conflicts come to the attention of the Council.

Council on Foods

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.
FRANKLIN C. BING, Secretary.

ANNUAL MEETING OF THE COUNCIL ON FOODS

The Council on Foods held its annual meeting at the Association headquarters on March 17, 1938. Dr. Bailey, who has served on the Council since its inception, was unable to attend because of illness. The following members were present: Drs. F. C. Bing, Joseph Brennemann, Morris Fishbein, George Cowgill, P. C. Jeans, Howard B. Lewis, J. S. McLester, Lydia J. Roberts, Mary Swartz Rose and Russell M. Wilder. Others present included Dr. Olin West, Secretary and General Manager of the American Medical Association; Dr. E. M. Nelson, Chief of the Vitamin Division, Food and Drug Administration; Dr. W. C. Woodward, Director of the Bureau of Legal Medicine; Dr. Paul Nicholas Leech, Director of the Division of Drugs, Foods and Physical Therapy, and Drs. Ruth Cowan Clouse and Majorie Pickens of the Council office.

Dr. Fishbein was reelected Chairman and Dr. Lewis was elected Vice Chairman.

The present work and future developments of the Council on Foods were discussed at some length. It has been found necessary in the last two years to limit somewhat the scope of products to be considered, because of the vast number of submissions and the limitation in facilities. As a result, several of the "natural foods" have been placed on the exempted list. The advisability of continuing consideration of sugars and homogenized milks was discussed and it was decided that, in view of the apparent necessity to moderate some of the claims which are being made for these foods, it would be well to retain them on the list of products considered and to "accept" those products which comply with the Rules and Decisions of the Council.

Ice creams, sherbets and ices were placed on the "exempted" list approximately a year and a half ago. One result of this action has been the formation of an Association of Quality Ice Cream Producers, which has established high sanitary and advertising standards for its members. The Council looks favorably on the general policy of this type of organization, and while it will not be possible to grant the use of the seal to appear on the cartons and in the advertising for the products of the member firms, as requested by the association, the Council voted to allow the members to incorporate on their cartons and in other advertising a uniform statement (without the seal) that the method of manufacture and the advertising claims are acceptable to the Council on Foods (after the Council has considered them).

A progress report on the series of articles on vitamins which is appearing currently in THE JOURNAL under joint sponsorship with the Council on Pharmacy and Chemistry was given. This series will consist of more than thirty articles and will be made

available in book form as soon as all of the reviews have appeared. Opportunity will be afforded authors to bring their bibliographies up to date before the book is published.

Work on the book Accepted Foods has been progressing and it is planned to publish this volume soon.

The following additional topics which were discussed during the meeting may be of interest to physicians, manufacturers and the general public:

Vitamin D Requirements of Babies Born Prematurely.—Consideration was given to the claim made by manufacturers of infant feeding preparations containing vitamin D that the use of some of them will prevent rickets in babies born prematurely. The referee, in discussing this question, observed that rickets in premature infants is not prevented by an amount of vitamin D which is less than that required for full term infants. After the first few weeks of life the requirement of the premature infant should approach that of the full term infant. The vitamin D requirement of the prematurely born infant is not easily determined because of the difficulty of supplying ample amounts of calcium and phosphorus during the first few weeks of extra-uterine life. It is well known that it is difficult for a premature baby to ingest sufficient calcium to permit adequate retention. There is evidence that prevention of rickets in premature infants may be accomplished by administering about 70 U. S. P. units of vitamin D per kilogram of body weight. For adequate retention of calcium and phosphorus more vitamin D may be necessary. From evidence available it can be concluded that the vitamin D requirements of prematurely born infants are satisfied by from 600 to 800 U. S. P. units of vitamin D fed in dispersed form, which is approximately twice the requirement (for prevention of rickets and for growth) of the majority of full term infants. Thus, the claim that a preparation which provides approximately 70 U. S. P. units of vitamin D per kilogram is antirachitic for premature babies is acceptable, although physicians should realize that, in the light of present knowledge, somewhat more vitamin D may be desirable for adequate retention of calcium.

Vitamin D and Growth.—In its study of the vitamin D requirements of infants, the Council distinguished between the amount of vitamin D necessary to prevent rickets and the greater amount which is necessary in order to permit optimal retention of calcium and phosphorus. As far as normal, full term infants are concerned, milk containing 135 U. S. P. units per quart usually will prevent rickets. Milk containing 400 U. S. P. units of vitamin D per quart obviously supplies somewhat more than the amount which usually is required to prevent rickets. The question has been raised whether or not vitamin D milk containing 400 U. S. P. units of vitamin D per quart permits good growth. It has long been known that vitamin D is a growth factor, like many other dietary essentials. There is evidence also that infants receiving customary quantities of milk which contains 400 U. S. P. units of vitamin D per quart exhibit good growth. The Council voted that this claim be recognized.

The Nutritional Significance of Foods (Other Than Milk) Commonly Fed During the First Year of Life.—Manufacturers of cereal products commonly used in infant feeding have advanced the claim that their respective products are baby's "first solid food." This statement is a relatively harmless bit of advertising puffery, but it is not entirely correct. Milk is a "solid" food just as much as any cereal product. The chief objection to the phrase, however, is the reference to any particular product as the "first" of the foods other than milk (and carbohydrate supplements). The referee discussed the general problem of infant feeding and the necessity of supplying the infant with suitable amounts of vitamins A, B₁, C and D and with iron and the other substances which foods supply. The place of orange juice, cod liver oil, cereals, vegetables, fruits and egg yolk in the diet of the infant was discussed.

A report on this topic will be prepared for publication. The Council voted, on the basis of evidence presented, that manufacturers of ordinary cereal products be requested to modify their claims to indicate that cereal preparations are "among baby's first solid foods" or that an individual product is "one of baby's first solid foods."

Caffeine and Theobromine in Foods.—The question of whether or not beverages containing caffeine and theobromine may be used by children is a perennial one. Unfortunately, it does not seem possible to specify a maximum amount of caffeine and theobromine which may be present in a product recommended for children. The habits and customs of different people vary greatly and the problem is complex. It is generally recognized that unrestricted quantities of tea, coffee and other purine containing beverages are not desirable for children. It is likewise generally recognized that a child should drink milk. Because a child will take only a limited amount of fluid material in a day, it is important that coffee, tea and other purine containing beverages do not replace milk.

The Problem of Lead in Foods.—The Council has sponsored some investigations on the lead problem during the last year and it is planned to continue these studies and to publish reports from time to time on the status of knowledge of this question.

Emulsifying Agents in Foods.—Certain foods, processed cheese and oleomargarine in particular, contain emulsifying agents. Formerly these emulsifying agents consisted of inorganic phosphates, lecithin and other well known substances. More recently a synthetic product known as monostearyl sodium sulfoacetate and frequently described as a "derivative of glycerin" has been much used. Reports of experiments indicate that this derivative of glycerin should be digested to glycerin, stearic acid and sodium sulfoacetate, the first two of which are harmless and the third of which appears to be excreted unchanged. It is considered improbable that sodium sulfoacetate in quantities likely to be ingested would have any toxic effect, either acute or cumulative, though no direct experiments concerned with either the digestion or fate in metabolism of the "derivative of glycerin" are available. The Council voted to prepare a report providing information concerning the newer emulsifying agents with a view to publication and later incorporation in the book *Accepted Foods*. The Council regards the name "derivative of glycerin" as nonspecific, indefinite and somewhat misleading because it includes all fats and lecithin. The more definite chemical name sodium monostearosulfoacetate will henceforth be used by the Council in the enumeration of ingredients of oleomargarins.

Conversion Factors for Changing Sherman Units of Vitamin A into International Units, and Problems Relating Thereto.—Data regarding the vitamin A content of most food products have been reported in terms of Sherman units. These units depend on the growth response of experimental animals which is subject to variation in different laboratories and at different times in the same laboratory. The Sherman unit therefore has no fixed value. It is now generally considered that the estimation of vitamin A in terms of international (or U. S. P. units) provides a means of compensating for a number of the variables inherent in the older method. According to the international system, the unit amount of vitamin A is defined as that which is contained in a definite amount of standard substance. The vitamin A content of a food product is determined by comparing the growth response of animals receiving a substance tested with the growth response of animals simultaneously fed the standard reference material. Thus, variations in growth due to unsuspected variations in composition of diets and other factors cancel out and the international unit becomes a relatively fixed value.

In 1933 the U. S. P. Vitamin Advisory Board reported that, on the basis of evidence then available, 1 Sherman unit appeared to be equal to about 1.4 international units. This was not an official factor but was widely adopted at that time for the conversion of Sherman to international units both in the drug and food fields. From evidence which has later accumulated in various laboratories, it now appears that 1 Sherman unit may be equal to from 1.4 international units to 0.5 international unit. A factor for the conversion of one unit into another is not necessary at the present time for pharmaceutical products, because there are relatively few of these and the potency can be determined by the U. S. P. method. In calculations for nutritional purposes, however, it will be necessary for some time to come to convert one unit into another. It is not possible, and because of the nature of the problem it will not be

possible, to select a single factor which is entirely satisfactory. It is the consensus of the Council, after reviewing available data, that the most probable relationship is 1 Sherman unit equals from about 0.66 to 0.80 international unit. A more detailed report is being prepared for publication. It will suffice here to give but one example of the importance of reviewing the evidence on this topic. As a standard allowance for the vitamin A requirements of an adult, various authorities have, in the past, suggested about 3,000 Sherman units. The question then arises: How many international units is this amount of vitamin A equivalent to? Because of the variability of the factors reported, this would be from 1,500 to 4,200 international units of vitamin A. The higher value, 4,200 international units, would be preferable as a standard dietary allowance but it would be well to know how liberal this amount actually is.

The Iodine Content of Iodized Salt.—In its General Decision "Iodized Salt, and Goiter an Iodine Deficiency Disease," the Council stated, "An accepted iodized salt shall contain one part sodium or potassium iodide per 5,000 parts salt (approximately 160 parts iodine per million parts salt), or iodine equivalent of any other suitable iodine compound." Latterly the opinion has been expressed by some investigators that the amount of iodine in iodized salt could well be decreased. The value of iodized salt (as defined by the Council) in the prevention of simple goiter has been demonstrated. It also is known that the ingestion of additional iodides by some persons, those with adenomatous goiter, for example, is harmful, but in reviewing available evidence there is no report that harm has come from the use of iodized salt. The Council decided, therefore, that for the present the amount of iodine in accepted brands of iodized salt should be continued at one part of sodium or potassium iodide to 5,000 parts of salt. It is planned also to prepare and publish a report on iodized salt in which these questions are discussed at greater length. The Council emphasizes that persons over 30 years of age with any swelling of the throat should not use iodized salt unless they do so under the directions of a competent physician.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

MIAMI VALLEY, DA LEE, SPRING FARM, PITCHERS BEST, AND SHADY NOOK BRANDS EVAPORATED MILK

Manufacturer.—Westerville Creamery Company, Covington, Ohio.

Description.—Canned, unsweetened evaporated milk.

Manufacture.—The raw milk is inspected, tested for butter-fat content, preheated, evaporated under vacuum, homogenized, cooled, and standardized for fat and total solids content. The evaporated milk is automatically filled into cans; the cans are sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 73.9%, total solids 26.1%, ash 1.3%, fat (ether extract) 7.8%, protein (N \times 6.38) 6.8%, lactose (by difference) 10.2%.

Calories.—1.4 per gram; 40 per ounce.

MRS. PALEY'S BABY FOOD—STRAINED PEAS

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, sieved peas, slightly seasoned with salt.

Manufacture.—Selected canned peas are sieved, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 84.1%, total solids 15.9%, ash 1.2%, fat (ether extract) 0.3%, protein (N \times 6.25) 4.7%, reducing sugars as dextrose—trace, sucrose 2.9%, crude fiber 0.6%, total carbohydrates other than crude fiber (by difference) 9.1%, calcium (Ca) 0.015%, phosphorus (P) 0.059%, iron (Fe) 0.001%.

Calories.—0.6 per gram; 17 per ounce.

SATURDAY, JULY 9, 1938

THE ROENTGENOLOGIST, THE PATHOLOGIST AND THE ANESTHETIST UNDER HOSPITAL INSURANCE PLANS

One of the most significant actions taken by the House of Delegates in San Francisco concerned the relationship of three professional groups—roentgenologists, pathologists, anesthetists—to various hospital insurance plans. Several resolutions which were offered from various sections of the country were considered by the Council on Medical Education and Hospitals. The Council in its report said:

The proposers of these resolutions, the delegates from the Massachusetts Medical Society, members of the California Medical Association and others met with the Council to express their views concerning the problems that concern the practice of medicine in hospitals by radiologists, pathologists and anesthetists. These problems have been rendered more acute by the rapid extension of systems of group hospital insurance within the last few years. The Council believes that these problems are of vital concern to the medical profession; that unwise decisions at this time may lead to consequences that would be disastrous to physicians and to the public alike, and that, therefore, a serious study should be made of existing relationships between hospitals and the physicians practicing therein, especially in the departments of anesthesia, radiology, pathology and physical therapy, with a view to standardizing the relationship of these services to the hospital and, where necessary, of reaffirming the principles of ethics involved.

The Council recommends that it, jointly with the Bureau of Medical Economics, be authorized to undertake these studies and to confer with other interested agencies, in order that it may be in a position to establish ethical standards for the practice of medicine by physicians holding positions in hospitals and to prevent the exploitation of either the public or the profession. If during this study it is revealed that hospitals registered and approved by the Council are exploiting the public or the profession, such approval may be revoked.

This report of the Council on Medical Education and Hospitals was adopted by the House of Delegates of the American Medical Association. Therefore, during the coming year a suitable study will be made and recommendations no doubt will be drawn up for submission to the House of Delegates at the next annual session.

Until new recommendations are made and until the House of Delegates has adopted them, the policy of the Association in relationship to these matters remains

unchanged. Should there be doubt as to the policy of the American Medical Association in this connection it is well to remember the action taken by the House of Delegates at San Francisco, which reads:

Since . . . some state and county medical societies may find it necessary to develop preferable procedures for supplying the needs where medical services are insufficient or unavailable, it is urged that these medical societies be guided in the development of these procedures by the ten principles adopted by the House of Delegates in 1934. The application of these ten principles to specific suggestions or proposals for the organization of medical services may be facilitated by utilizing the method of direct cash payments to individual members. Your committee unanimously concurs in the suggestion and recommends that the American Medical Association adopt the principle that in any place or arrangement for the provision of medical services the benefits shall be paid in cash directly to the individual member. Thus, the direct control of medical services may be avoided. Cash benefits only will not disturb or alter the relations of patients, physicians and hospitals.

Your committee has considered in detail that portion of the report of the Board of Trustees devoted to the Bureau of Medical Economics under the heading "Group Hospitalization" and also the separate statement of the Bureau of Medical Economics entitled "Group Hospitalization Insurance." Your committee commends the clarity and forcefulness of these statements and recommends that the ten principles adopted in 1934 as the policy of the American Medical Association be amplified by the addition of the following statement to Principle 4:

If for any reason it is found desirable or necessary to include special medical services such as anesthesia, radiology, pathology or medical services provided by outpatient departments, these services may be included only on the condition that specified cash payments be made by the hospitalization organization directly to the subscribers for the cost of the services.

Disapproval of the inclusion of special medical services on a service basis in hospitalization insurance contracts will then be explicit but a constructive alternative arrangement will be possible.

These actions should make clear the point of view of the American Medical Association in this regard.

Recent apparently inspired news items have asserted that "the American Medical Association and various groups within the profession oppose the hospital insurance system which protects 1,600,000 Americans." The American Medical Association has never opposed hospital insurance; several of its constituent medical societies have been responsible for the development of hospital insurance plans. The plans prevailing in Washington, D. C., St. Louis, Oakland, Calif., and the statewide plans in Alabama and North Carolina were inaugurated by medical societies. In many other localities, medical societies are participating in the operation of hospital insurance plans.

The medical profession is certainly opposed to those undesirable types of hospital insurance plans which violate state insurance laws or state laws governing medical practice, and to those plans promoted for individual gain. Most of the plans which violated state insurance laws or which were operated for personal gain have been discontinued or reorganized. However, many hospital service plans continue to ignore state medical practice acts which require persons to possess certain educational requirements and pass an examination before they can offer to diagnose illnesses or treat the sick. Hospitals and hospital insurance corporations

cannot fulfil these requirements. In most states the courts have therefore recognized that it is contrary to good public policy for a corporation to attempt to practice medicine by hiring physicians to practice medicine for the corporation. Physicians have always objected to those arrangements whereby a corporation (and most hospitals are corporations) attempts to sell the services of roentgenologists, pathologists and anesthetists in a manner which results in a profit for the corporation or places the directors of the corporation in control of the personal relations between the patient and his physician. Similar undesirable relations are created when a corporation attempts to practice any profession. Consequently, the courts have also recognized that a corporation cannot practice law or hire lawyers to practice law for it. The same holds true for dentistry. These principles are maintained to give the individual person reasonable assurance that he will receive competent services from physicians, lawyers and dentists.

The action taken by the House of Delegates in San Francisco holds that it is desirable to permit each person to receive the benefits from a hospital insurance system in cash so that he may purchase his own medical services from whatever source he may desire. When the individual himself pays for the services he receives he can be assured of adequate and satisfactory services; otherwise he can refuse to make the payment. Under the cash-to-the-insured payment arrangement, which is the long-established method used by accident and health insurance companies, the insured person receives a definite number of dollars with which he can purchase services that are satisfactory to him. He does not have to accept whatever services may be offered by the insuring organization. The rights of the patient certainly are superior to those of the hospital, the corporation or any other interest.

ACTIVE IMMUNIZATION AGAINST TETANUS

The prophylactic use of tetanus antitoxin in the production of passive immunity, while valuable, has presented certain disadvantages which have led to continued efforts to produce active and more permanent protection. The initial difficulty in the immunization of man against tetanus, according to Boyd,¹ lies in the lack of a suitable immunizing agent. Most of the recent work has been carried out with altered toxin termed anatoxin by Ramon but now more commonly known as toxoid. In spite of the many efforts in this direction, however, there is at present no fixed standard for tetanus toxoid except that adopted in France. The dose has varied but inoculation by the subcutaneous route has proved reasonably satisfactory. The duration of active immunity conferred by inoculation with toxoid has been so closely connected with preparation of the

material, the size and frequency of the injection and other factors as to have varied widely in the hands of different investigators. From the Royal Army Medical College, Boyd reports direct experiences in immunization against tetanus. The first product used was tetanus toxoid-antitoxin floccules prepared along the same lines as diphtheria toxoid-antitoxin floccules. In the small group of volunteers treated the antitoxin production was negligible and in two months only a faint trace was found in four of the seven. Nine months after inoculation with the floccules, three of the volunteers were given a dose of 1 cc. of formol-toxoid. Two of these subjects tested after a month showed no less than two units of antitoxin per cubic centimeter of serum, while the third, not tested until fifty-six days after reinoculation, showed at that time between ten and twenty units. It seemed therefore that inoculation with floccules establishes a basal immunity, even though it fails to produce antitoxin in the serum.

Another group of thirteen volunteers was given a preliminary dose of 1 cc. of tetanus toxoid (formol-toxoid). From twenty-one to twenty-six days later, five were given a second dose of 1 cc. and a month thereafter samples of blood were tested for antitoxin. The titers at this time varied from 0.005 to 0.02 unit of antitoxin per cubic centimeter of serum, a concentration which cannot be regarded as adequate. The remaining eight men were given a second dose from six to seven weeks after the first and tested four weeks later with more satisfactory results. A further group was therefore treated similarly, and figures ultimately were available on thirty treated in this manner. The titer was between 0.01 and 0.1 unit of antitoxin per cubic centimeter of serum in three, from 0.1 to 1 unit in twenty-one, and 1 unit and over in six. These results are certainly much better than those obtained when the two doses were given at an interval of three weeks, and the average is far above the level believed to confer a protection against tetanus. The antitoxin titers compare favorably in fact with those from Ramon's three dose method and also from inoculation with two doses of alum precipitated toxoid, except when the latter are administered at wide intervals. Recommendations have accordingly been made to introduce this measure on a voluntary basis into the British army. The more extensive experience which will be thus obtained will doubtless provide valuable evidence of this particular procedure of active immunization.

In another interesting investigation of the subject recently published, Gold² administered two 0.5 cc. doses of tetanus toxoid alum precipitated, given 645 days apart to fifty adult workers. The later titration of the antitoxin titer of the serum from eleven members of this group showed considerable individual variability in the amount of antitoxin produced and lost in the course of active immunization. Similar results were obtained

1. Boyd, J. S. K.: Active Immunization Against Tetanus, *J. Roy. Army M. Corps* 70:289 (May) 1938.

2. Gold, Herman: Active Immunization Against Tetanus By Means of Tetanus Toxoid Alum-Precipitated Refined, *J. Lab. & Clin. Med.* 23: 903 (June) 1938.

with other groups given the toxoid at different intervals and tested after different periods. It could be concluded nevertheless, this author believed, that a protective antitoxin titer of one unit or more develops in from five to fourteen days after an injection of a second dose of alum toxoid, even when the latter is given two years after the first dose. The duration of the protective level varies, however, and may disappear within ninety days or may last over two years. The antitoxin titer can be raised to a protective level by a further injection of alum toxoid. The most important question requiring further investigation, he concluded, is the determination of the actual amount of antitoxin necessary to protect against tetanus. Furthermore, if an infection occurs during an interval before the basic course of immunization is completed or within a few days after the second injection of alum toxoid when the antitoxin level of the blood has not yet reached 0.1 unit, it may be necessary to resort to passive immunization in order to insure full protection against tetanus. These are fundamental investigations. The attempt to produce active immunization to tetanus is of significant and practical importance, and the possible development of war injuries on a large scale lends an increasing importance to the prophylactic effort.

Current Comment

AWARD TO AMERICAN MEDICAL ASSOCIATION RADIO PROGRAM

The National Broadcasting Company has just issued a folder entitled NBC . . . Cum Laude, in which are listed awards to noteworthy radio programs broadcast over the National Broadcasting Company networks. The Institute for Education by Radio, at the ninth annual conference at Columbus, Ohio, heard transcriptions of more than 200 entries and made the following first awards to programs broadcast over the coast to coast networks of the National Broadcasting Company: Science in the News, produced by the University Broadcasting Council; The Story Behind the Headlines, by the American Historical Association; The NBC Home Symphony; Town Meeting of the Air, by Town Hall Inc., and Your Health, by the American Medical Association. Honorable mention was awarded to the University of Chicago Round Table and The World Is Yours (the Story of Electricity), produced by the U. S. Office of Education. All these programs were produced over networks of the National Broadcasting Company and with the cooperation of the educational divisions of that company. The inclusion of the educational radio program of the American Medical Association in an honor group selected by educational and radio experts is gratifying. This program has been broadcast for three seasons in dramatized form, and active plans are under way for a new series for the fall, winter and spring of 1938-1939. The principal need of this program now is a broader audience and

more local outlets. County medical societies and auxiliaries have an opportunity to call the attention of this award of merit to the managers of local stations and to make efforts to interest such managers in the Your Health program as an exceptional sustaining educational feature for 1938-1939. A sustaining program as distinguished from a commercial program is one from which the networks and the local stations derive no revenue but which they contribute as a part of their function in broadcasting "for the public interest, convenience and necessity." The National Broadcasting Company cannot assure the broadcasting of network programs over stations not owned by the company, even though such stations have NBC network affiliations. The local outlets must be procured largely on the basis of local effort, through which local interest in the program can be developed. All principals of high schools and junior high schools should be given full information about the program. Informative folders prepared by the Bureau of Health Education will soon be available and will be sent gratis in quantities which can be put to good local use, on request.

TUBERCULOSIS STUDIES IN TENNESSEE

Today, with diminishing mortality from pulmonary tuberculosis, intensified emphasis is placed on early diagnosis. An example of the importance attached to early diagnosis is manifest in the study by Stewart and his collaborators¹ on tuberculous infection, morbidity and mortality in 468 households in Williamson County, Tenn. In addition to the individuals through whom attention was drawn to the family, 3,169 household contacts were examined by detailed history, physical examination, roentgen study and the tuberculin test. Of the household contacts under 15 years of age, a positive reaction to tuberculin was observed in a definitely higher proportion of those exposed to patients with positive sputum than in those exposed to other types or stages of tuberculosis. Except in the case of exposure to open tuberculosis, in fact, the positive reactions to tuberculin in the age groups from 5 to 14 were approximately the same as in the general school population. Evidence of infection as shown by roentgen examination was higher in those exposed to sputum positive patients before middle age than in later years. The possibilities of death from tuberculosis were considerably greater for the contacts of sputum positive patients than for the white population of Tennessee as a whole. Furthermore, the excess risk was concentrated in the younger age groups. The development of manifest tuberculosis and death from tuberculosis were both twice as frequent for those exposed to sputum positive patients as for those exposed to patients with manifest tuberculosis without positive sputum. Finally, it was found that the annual tuberculosis attack rate for the household contacts in the ten year period following exposure to open tuberculosis was slightly greater than 1 per cent a year—a rate approximately the same as noted in Philadelphia and in Cattaraugus County, N. Y.

ORGANIZATION SECTION

PROCEEDINGS OF THE SAN FRANCISCO SESSION

MINUTES OF THE EIGHTY-NINTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT SAN FRANCISCO, JUNE 13-17, 1938

(Concluded from page 64)

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Francis G. Blake, New Haven, Conn.

In the absence of the secretary, Dr. Fred M. Smith, Iowa City, Dr. Gordon E. Hein, San Francisco, acted as secretary.

Dr. George E. Fahr, Minneapolis, read a paper on "The Treatment of Cardiac Irregularities." Discussed by Drs. William J. Kerr, San Francisco; Horace M. Korn, Iowa City; S. A. Weisman, Minneapolis; Wilhelm Dressler, Vienna (Berkeley, Calif.), and George E. Fahr, Minneapolis.

Drs. Donald E. Griggs, Charles B. Coggin and Newton G. Evans, Los Angeles, presented a paper on "Right Ventricular Hypertrophy and Congestive Failure in Chronic Pulmonary Disease." Discussed by Drs. John J. Sampson, San Francisco, and Donald E. Griggs, Los Angeles.

Dr. Walter L. Biering, Des Moines, Iowa, delivered the Frank Billings Lecture entitled "Focal Infection—A Quarter Century Survey."

Dr. M. A. Blankenhorn, Cincinnati, read a paper on "The Present Status of the Serum Therapy of Lobar Pneumonia."

THURSDAY, JUNE 16—AFTERNOON

Dr. Albert H. Rowe, Oakland, Calif., read a paper on "Bronchial Asthma: Its Diagnosis and Treatment." Discussed by Drs. Charles H. Eyermann, St. Louis; George Piness, Los Angeles; John Francis Quinlan, San Francisco; Julian Cohn, Los Angeles, and Albert H. Rowe, Oakland, Calif.

Dr. Francis G. Blake, New Haven, Conn., read the chairman's address, entitled "A Further Evaluation of Artificial Pneumothorax in Lobar Pneumonia."

Drs. Martin H. Dawson and Ralph H. Boots, New York, presented a paper on "The Treatment of Rheumatoid Arthritis." Discussed by Drs. Ernest E. Irons, Chicago, and Russell L. Haden, Cleveland.

Dr. Bayard T. Horton, Rochester, Minn., read a paper on "The Outlook in Thrombo-Angiitis Obliterans." Discussed by Drs. F. E. Bollaert, East Moline, Ill., and Bayard T. Horton, Rochester, Minn.

Dr. Roy W. Scott, Cleveland, read a paper on "Hypertension: A Century After Bright." Discussed by Drs. T. H. Coffen, Portland, Ore.; Frank R. Nuzum, Santa Barbara, Calif., and Roy W. Scott, Cleveland.

Dr. Karl A. Menninger, Topeka, Kan., read a paper on "The Psychologic Factor in Disease." Discussed by Drs. Edgar V. Allen, Rochester, Minn.; Dwight L. Wilbur, San Francisco, and Karl A. Menninger, Topeka.

FRIDAY, JUNE 17—AFTERNOON

The following officers were elected: chairman, Dr. N. C. Gilbert, Chicago; vice chairman, Dr. L. H. Briggs, San Francisco; member of the American Board of Internal Medicine, Dr. Ernest E. Irons, Chicago.

Acting Secretary Hein read a note addressed to Dr. Fred M. Smith, stating that Dr. Walter J. Barlow passed away on Sept. 4, 1937.

Drs. Daniel B. Hayden and Edward L. Chainski, Chicago, presented a paper on "Tinnitus: Etiology and Evaluation of the Various Methods of Treatment." Discussed by Drs. Willard L. Wood, Chicago (read by the secretary in his absence), and Charles E. H. Bates, San Francisco.

Dr. Francis D. Murphy, Milwaukee, read a paper on "Acute Glomerular Nephritis with Special Reference to the Course and Prognosis: A Study of 150 Cases." Discussed by Drs. Thomas Addis, San Francisco; James S. McLester, Birmingham, Ala., and Francis D. Murphy, Milwaukee.

Drs. L. H. Newburgh and Jerome W. Conn, Ann Arbor, Mich., presented a paper on "A New Interpretation of Diabetes Mellitus in Obese, Middle Aged Persons: Recovery Through Reduction of Weight: First Report." Discussed by Drs. Bernard Smith, Los Angeles; J. W. Sherrill, La Jolla, Calif.; Frank N. Allan, Boston, and Jerome W. Conn, Ann Arbor, Mich.

Dr. Edward H. Rynearson, Rochester, Minn., read a paper on "The Treatment of Addison's Disease." Discussed by Drs. Herbert M. Evans, Berkeley, Calif., Lester J. Palmer, Seattle; Willard O. Thompson, Chicago, and Edward H. Rynearson, Rochester, Minn.

Drs. Willard O. Thompson and Norris J. Heckel, Chicago, presented a paper on "The Present Status of the Treatment of Undescended Testes." Discussed by Drs. Hans Lisser, San Francisco; E. Kost Shelton, Los Angeles, and Willard O. Thompson, Chicago.

Drs. John Russell Twiss and James H. Barnard, New York, presented a paper on "The Management of Biliary Tract Disease Associated with Disturbances in Cholesterol Metabolism: A Review of 100 Cases Treated Medically and Surgically." Discussed by Drs. Arthur L. Bloomfield, San Francisco, and John Russell Twiss, New York.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Hugh H. Trout, Roanoke, Va.

Drs. Waltman Walters and Edwin John Kepler, Rochester, Minn., presented a paper on "Surgical Lesions of the Adrenal Glands." Discussed by Drs. Howard C. Naffziger, San Francisco; Hans Lisser, San Francisco, and Waltman Walters, Rochester, Minn.

Dr. J. Eastman Sheehan, New York, read a paper on "The Use of Free Full-Thickness Skin Graft." Discussed by Drs. George W. Pierce, San Francisco; H. L. D. Kirkham, Houston, Texas, and J. Eastman Sheehan, New York.

Dr. Charles Scott Venable, San Antonio, Texas, read a paper on "Electrolysis: The Controlling Factor in the Use of Metals in Fractures." Discussed by Drs. Edgar L. Gilcreest, San Francisco; Leon O. Parker, San Francisco, and Charles Scott Venable, San Antonio, Texas.

Drs. Martin B. Tinker and Martin B. Tinker Jr., with the collaboration of Drs. A. T. Kerr and W. M. Sawdon, Ithaca,

N. Y., presented a paper on "Fracture of the Neck of the Femur." Discussed by Drs. Kellogg Speed, Chicago; Wallace I. Terry, San Francisco; Walter G. Stern, Cleveland, and Martin B. Tinker, Ithaca, N. Y.

Drs. George W. Swift and S. N. Berens, Seattle, presented a paper on "Cerebrocranial Injuries: Detailed Study of 1,433 Cases." Discussed by Drs. Harry E. Mock, Chicago, and George W. Swift, Seattle.

THURSDAY, JUNE 16—MORNING

Dr. Arthur Carroll Scott, Temple, Texas, read a paper on "Early Differential Diagnosis of Breast Tumors." Discussed by Drs. Irvin Abell, Louisville, Ky.; James F. Percy, Los Angeles, and Arthur Carroll Scott, Temple, Texas.

Dr. Hugh H. Trout, Roanoke, Va., read the chairman's address, entitled "Carcinoma of the Breast."

Dr. Howard M. Clute, Boston, read a paper on "Gastroduodenostomy for Certain Duodenal Ulcers." Discussed by Drs. Robert S. Dinsmore, Cleveland; Harold L. Thompson, Los Angeles; Moses E. Steinberg, Portland, Ore., and Howard M. Clute, Boston.

Dr. John Oscar Bower, Philadelphia, read a paper on "Routine Operations versus Scientific Management of Spreading Peritonitis Complicating Acute Perforative Appendicitis." Discussed by Drs. Harold P. Totten, Los Angeles; David A. Willis, Chicago; W. D. Haggard, Nashville, Tenn., and John Oscar Bower, Philadelphia.

Drs. Grover Cleveland Penberthy, Charles G. Johnston, R. J. Noer and J. C. Kenning, Detroit, presented a paper on "The Use of Small Intestine Decompression in the Treatment of Intestinal Obstruction." Discussed by Drs. Dwight L. Wilbur, San Francisco; Frederick A. Collier, Ann Arbor, Mich., and Charles G. Johnston, Detroit.

Drs. Fred W. Rankin, Lexington, Ky., and John Stewart Stage Combined Abdominoperineal Resection of the Rectum for Cancer." Discussed by Drs. Thomas M. Joyce, Portland, Ore.; Harvey B. Stone, Baltimore; Thomas E. Jones, Cleveland, and Fred W. Rankin, Lexington, Ky.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Dr. Henry W. Cave, New York; vice chairman, Dr. Fred W. Bailey, St. Louis; secretary, Dr. Arthur W. Allen, Boston; member of the executive committee, Dr. Hugh H. Trout, Roanoke, Va. Drs. Fred W. Rankin, Lexington, Ky., and John Stewart Rodman, Philadelphia, were appointed to succeed themselves for a period of two years as representatives of the Section on Surgery on the American Board of Surgery.

Drs. Albert O. Singleton and Truman G. Blocker Jr., Galveston, Texas, presented a paper on "The Problem of Disruption of Abdominal Wounds and Postoperative Hernia." Discussed by Drs. R. L. Sanders, Memphis, Tenn.; Alton Ochsner, New Orleans; Carl R. Steinke, Akron, Ohio; Frank K. Boland, Atlanta, Ga., and Albert O. Singleton, Galveston, Texas.

Dr. Charles Eaton Phillips, Los Angeles, read a paper on "Mediastinal Infections Due to Esophageal Perforations." Discussed by Drs. Simon Jesberg, Los Angeles, and Charles Eaton Phillips, Los Angeles.

Dr. Claude Frank Dixon, Rochester, Minn., read a paper on "Management of Intestinal Fistulas." Discussed by Drs. Gunther W. Nagel, San Francisco; Alton Ochsner, New Orleans, and Claude Frank Dixon, Rochester, Minn.

Drs. Frederick A. Collier and Howard C. Jackson, Ann Arbor, Mich., presented a paper on "Surgical Aspects of Hypoglycemia Associated with Liver Damage." Discussed by Drs. Emile F. Holman, San Francisco; Frank N. Allan, Boston; Theodore L. Althausen, San Francisco, and Frederick A. Collier, Ann Arbor, Mich.

Drs. Amos R. Koontz and Richard T. Shackelford, Baltimore, presented a paper entitled "Does Ether Narcosis Protect from Anaphylactic Shock?" Discussed by Drs. Franklin I. Harris, San Francisco, and Amos R. Koontz, Baltimore.

SECTION ON OBSTETRICS AND GYNECOLOGY

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. E. D. Plass, Iowa City.

Drs. Eva F. Dodge, Montgomery, Ala., and Thomas T. Frost, Winston-Salem, N. C., presented a paper on "The Relation Between Blood Plasma Proteins and Toxemias of Pregnancy: A Preliminary Report." Discussed by Drs. Boyd Harden, Burlington, N. C.; Thomas Addis, San Francisco, and Eva F. Dodge, Montgomery, Ala.

Dr. Francis L. McPhail, Great Falls, Mont., read a paper on "Toxemias of Pregnancy: Cause and Treatment." Discussed by Drs. P. J. Carter, New Orleans; Lyle G. McNeile, Los Angeles, and Francis L. McPhail, Great Falls, Mont.

Dr. Frederic Schreiber, Detroit, read a paper on "Cyanosis of the Newborn and Associated Cerebral Injury." Discussed by Drs. C. B. Courville, Los Angeles; J. C. Litzberg, Minneapolis, and Charles Edwin Galloway, Evanston, Ill.

Dr. Richard Torpin, Augusta, Ga., read a paper on "Study of Placental Site and Intra-Uterine Relationship by Original Method of Amniotic Sac Distention: Report of 400 Cases." Discussed by Drs. L. A. Calkins, Kansas City, Mo.; James R. Reinberger, Memphis, Tenn., and Richard Torpin, Augusta, Ga.

Dr. Donald J. Thorp, Seattle, read a paper on "Study of the Pelvic Joints During Pregnancy and Labor." Discussed by Drs. Alice F. Maxwell, San Francisco, and Donald J. Thorp, Seattle.

Drs. Emil Bogen and Jane Skillen, Olive View, Calif., presented a paper on "Pregnancy and Tuberculosis." Discussed by Drs. J. C. Irwin, Los Angeles, and Emil Bogen, Olive View, Calif.

The talking motion picture "The Birth of a Baby" was presented.

THURSDAY, JUNE 16—AFTERNOON

Dr. Joseph L. Baer, Chicago, read a paper on "The Cervix Uteri in Obstetrics and Gynecology." Discussed by Drs. Edward A. Schumann, Philadelphia; George W. Kosmak, New York; Goodrich C. Schauffler, Portland, Ore., and Joseph L. Baer, Chicago.

Dr. William T. Black, Memphis, Tenn., read a paper on "Consideration of Good and Bad Results in the Treatment of Chronic Cervicitis." Discussed by Drs. R. G. Craig, San Francisco; Harvey B. Matthews, Brooklyn; Channing W. Barrett, Chicago; Leo P. Fitzgerald, St. Louis, and William T. Black, Memphis, Tenn.

Dr. Donald C. Collins, Los Angeles, read a paper on "The Management of Tuberculosis of the Cervix Uteri." Discussed by Drs. Ludwig A. Emge, San Francisco; Henry Schmitz, Chicago, and Donald C. Collins, Los Angeles.

Dr. Charles Edwin Galloway, Evanston, Ill., read a paper on "Color Photography of the Uterine Cervix." Discussed by Drs. J. M. Bruner, Des Moines, Iowa, and Charles Edwin Galloway, Evanston, Ill.

Drs. Virgil S. Counsellor and Robert E. Bedard, Rochester, Minn., presented a paper on "Uterine Myomectomy: Analysis of Indications and Results in 500 Cases." Discussed by Drs. Frank W. Lynch, San Francisco, and Virgil S. Counsellor, Rochester, Minn.

Dr. E. D. Plass, Iowa City, read the chairman's address, entitled "Undergraduate Obstetric Teaching."

FRIDAY, JUNE 17—AFTERNOON

The following officers were elected: chairman, Dr. Harvey B. Matthews, Brooklyn; vice chairman, Dr. Ludwig A. Emge, San Francisco; secretary, Dr. Norman F. Miller, Ann Arbor, Mich.; delegate, Dr. George Gray Ward, New York; alternate, Dr. J. P. Pratt, Detroit.

The secretary reported that the executive committee recommended that the Section on Obstetrics and Gynecology endorse the action of the Committee on Maternal Welfare in supporting the film "The Birth of a Baby."

On motion regularly made and seconded, it was voted that the section endorse the action of the Committee on Maternal Welfare.

The secretary read a resolution to be offered to the Council on Pharmacy and Chemistry and the Council on Physical Therapy of the American Medical Association as follows:

WHEREAS, The House of Delegates of the American Medical Association at its Annual Meeting in Atlantic City in 1937 adopted three recommendations offered by the Association's Committee to Study Contraceptive Practices and Related Problems, namely:

1. To make clear to physicians their legal rights in relation to the use of contraceptives;
2. That investigation of materials, devices and methods recommended or employed for the prevention of conception be made, and the results of such investigation be published for the information of the medical profession;
3. That the Council on Medical Education and Hospitals of the American Medical Association be requested to promote thorough instruction in our medical schools with respect to various practices pertaining to fertility and sterility, due attention being paid to their positive as well as their negative aspects; and

WHEREAS, The Section on Obstetrics and Gynecology of the American Medical Association knows of the report of progress issued by the Association during the past year following up these recommendations; be it

Resolved, That the Section on Obstetrics and Gynecology of the American Medical Association heartily endorses the adoption of these recommendations, congratulates the Association on its stand, and in view of the urgency of the situation requests early action in accordance with said recommendations.

On motion regularly made and duly seconded, it was voted to adopt the resolution.

It was voted to appoint Dr. Harvey B. Matthews, Brooklyn, delegate to the annual meeting of the New York Obstetrical Society.

Dr. Arthur H. Curtis, Chicago, read a paper on "Anatomic Factors in the Pathogenesis and Treatment of Urethrocele and Cystocele." Discussed by Drs. W. T. Dannreuther, New York; G. D. Royston, St. Louis; Joseph L. Baer, Chicago, and Arthur H. Curtis, Chicago.

Dr. Goodrich C. Schauffler, Portland, Ore., read a paper on "Practical Deductions from the Management of 225 Cases of Infection of the Immature Vagina." Discussed by Drs. C. F. Fluhmann, San Francisco; H. Close Hesselstine, Chicago; Richard Torpin, Augusta, Ga., and Goodrich C. Schauffler, Portland, Ore.

Drs. Fred L. Adair, H. Close Hesselstine and Lucile Hac, Chicago, presented a paper on "Experimental Study of Behavior of Sulfanilamide." Discussed by Drs. Herbert O. Calvery, Washington, D. C.; J. P. Pratt, Detroit, and H. Close Hesselstine, Chicago.

Drs. Henry Schmitz, Herbert E. Schmitz and John Francis Sheehan, Chicago, presented a paper on "The Action of Measured Doses of 800 Kilovolt Roentgen Rays on Carcinomas of the Uterine Cervix." Discussed by Drs. D. G. Morton, San Francisco; Robert R. Newell, San Francisco; L. H. Garland, San Francisco, and Henry Schmitz, Chicago.

SECTION ON OPHTHALMOLOGY

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Parker Heath, Detroit.

Dr. Parker Heath, Detroit, read the chairman's address.

The chairman called for an executive session to consider a motion made by Dr. Edward Jackson, Denver, seconded by Dr. John Green, St. Louis, that a committee of three be appointed to consider the chairman's address. The motion was voted on and carried.

It was recommended by the executive committee that the section dedicate the volume of this section's meeting and proceedings to Dr. John E. Weeks, Portland, Ore., and Dr. Edward Jackson, Denver. The recommendation was adopted by a rising vote.

Drs. Phillips Thygeson, New York, and Polk Richards, Albuquerque, N. M., presented a paper on "The Nature of the Filtrable Agent of Trachoma." Discussed by Drs. Edwin William Schultz, Santa Clara, Calif.; Harry S. Gradle, Chicago, and Phillips Thygeson, New York.

Drs. Frederick H. Verhoeff and Merrill J. King, Boston, presented a paper on "Scleromalacia Perforans: Report of a Case in Which the Eye was Examined Microscopically." Discussed by Drs. Frederick A. Kiehle, Portland, Ore.; Samuel

P. Oast, New York; Arthur J. Bedell, Albany, N. Y.; Trygve Gundersen, Boston; Lloyd Mills, Los Angeles, and Frederick H. Verhoeff, Boston.

Dr. P. J. Leinfelder, Iowa City, read a paper on "Histopathology in Amblyopia Following Tryparsamide Therapy." Discussed by Drs. Frederick C. Cordes, San Francisco; Max Fine, San Francisco; John E. Weeks, Portland, Ore.; Otis A. Sharpe, San Francisco; Frederick H. Verhoeff, Boston; Edward Jackson, Denver, and P. J. Leinfelder, Iowa City.

Dr. Fred Loc, Rosebud, S. D., read a paper on "Sulfanilamide Treatment of Trachoma." Discussed by Dr. Harry S. Gradle, Chicago.

Dr. John M. Wheeler, New York, read a paper on "Ptosis Correction by Attachment of Orbicularis Strips to Superior Rectus." Discussed by Drs. John O. McReynolds, Dallas, Texas; John E. Weeks, Portland, Ore.; Warren D. Horner, San Francisco; C. Allen Dickey, San Francisco, and John M. Wheeler, New York.

THURSDAY, JUNE 16—MORNING

The chairman called for an executive session to consider the report by Dr. Albert C. Snell, Rochester, N. Y., on Visual Standards for Licensure to Operate Motor Vehicles. The report was adopted and referred to the House of Delegates.

The executive session was terminated on motion duly seconded and carried.

Dr. Edward Jackson, Denver, read a paper on "Theory and Use of Cross Cylinders." Discussed by Drs. Charles K. Mills, Woodland, Calif.; William H. Crisp, Denver; John Green, St. Louis; Henry B. Lemere, Beverly Hills, Calif., and Edward Jackson, Denver.

Dr. Albert C. Snell, Rochester, N. Y., read a paper on "Visual Acuity: Its Relation to Form Sense and the Application of This Relationship to Medicolegal Problems." Discussed by Drs. D. F. Harbridge, Phoenix, Ariz.; Ralph O. Rychener, Memphis, Tenn.; William H. Crisp, Denver; S. Judd Beach, Portland, Maine, and Albert C. Snell, Rochester, N. Y.

Drs. John E. L. Keyes and Harry Goldblatt, Cleveland, presented a paper on "Vascular Changes in the Eyes in Experimental Hypertension." Discussed by Drs. Arthur J. Bedell, Albany, N. Y.; William L. Benedict, Rochester, Minn., and John E. L. Keyes, Cleveland.

Dr. Hermann Burian, Hanover, N. H., read a paper on "Fusional Movements: Role of Peripheral Retinal Stimuli." Discussed by Drs. Avery M. Hicks, San Francisco; Walter H. Fink, Minneapolis; Frederick H. Verhoeff, Boston; K. C. Brandenburg, Long Beach, Calif.; Otto Barkan, San Francisco, and Hermann Burian, Hanover, N. H.

Drs. Conrad Berens and Donald W. Bogart, New York, presented a paper on "Postoperative Complication of Cataract Operations." Discussed by Drs. Watson W. Gailey, Jr., Bloomington, Ill.; Joseph L. McCool, San Francisco, and Conrad Berens, New York.

FRIDAY, JUNE 17—MORNING

Executive Session

On motion duly seconded and carried, the following resolution was adopted by the section:

Resolved, That the Section on Ophthalmology records its emphatic opposition to any measures such as the proposed State Humane Pound Law which will hinder or curtail animal experimentation as conducted by those fully qualified in biology and medicine.

Dr. Albert C. Snell, Rochester, N. Y., presented the report of the Committee on Compensation and Visual Economics. The report was accepted.

Dr. William L. Benedict, Rochester, Minn., read the report of the Committee on Optics and Visual Physiology. The report was accepted and the recommendations adopted.

The report of the Committee on the Knapp Testimonial Fund was presented by Dr. Parker Heath, Detroit. The report was accepted and the committee thanked.

Dr. Derrick Vail, Cincinnati, the secretary, reported for the Committee on Awarding the Knapp Medal that no award would be made this year.

Dr. Derrick Vail, Cincinnati, read the report of the Committee on National Museum of Ophthalmic Pathology, in the absence of the chairman, Dr. James S. Friedenwald, Baltimore. The report was accepted.

The report of the Committee on the American Board of Ophthalmology was read by Dr. William H. Crisp, Denver. The report was accepted.

Dr. Georgiana Dvorak Theobald, Oak Park, Ill., read the report of the Committee on Scientific Exhibit from the section. The report was accepted and the committee thanked.

Dr. Derrick Vail, Cincinnati, reported progress for the Committee to Cooperate with the National Committee on Prevention of Blindness. He also reported that some contact with the National Society for the Prevention of Blindness and the Social Security Board has been made and that the committee wished to be continued. It was moved, duly seconded and carried, that the report be accepted and the committee continued.

Dr. Arthur J. Bedell, Albany, N. Y., reported as delegate of the section to the House of Delegates. His report was accepted with thanks.

Dr. John Green, St. Louis, read the report of the Committee on the Museum of Ophthalmic History, in the absence of the chairman, Dr. Burton Chance, Philadelphia. The report was accepted.

Dr. Clifford B. Walker, Los Angeles, read the report of the Committee on Standardization of Drugs and Instruments. The report was accepted and the committee thanked.

A vote of thanks was extended to the Committee on Visual Standards for Operating Motor Vehicles. A vote of thanks was also extended to the local committee on arrangements.

The following officers were elected: chairman, Dr. S. Judd Beach, Portland, Maine; vice chairman, Dr. Frederick C. Cordes, San Francisco; secretary, Dr. Derrick Vail, Cincinnati.

Dr. Conrad Berens, New York, was appointed to fill a vacancy on the Committee on American Board of Ophthalmology.

Dr. Georgiana Dvorak Theobald, Oak Park, Ill., was reelected to fill the vacancy of chairman of the Committee for Scientific Exhibit from the Section. Dr. Theodore E. Sanders, St. Louis, and Dr. Derrick Vail, Cincinnati, were appointed as members of the committee.

To fill a vacancy on the American Committee (Joint) on Optics and Visual Physiology, Dr. Walter B. Lancaster, Boston, was reappointed for three years.

To the Joint Committee on Orthoptics, to represent the section, the following appointments were made: Dr. Derrick Vail, Cincinnati, chairman; Everett L. Goar, Houston, Texas, and Harold Gifford, Omaha.

To the Advisory Committee of Student Health Association, Dr. William L. Benedict, Rochester, Minn., was appointed.

To the Committee on Museum of Ophthalmic History, the following were appointed: Dr. Robert Sattler, Cincinnati; Dr. Frank H. Burch, St. Paul; Dr. John B. Weeks, Portland, Ore.; Dr. F. Phinizy Calhoun, Atlanta, Ga.; Dr. Adolph O. Pfingst, Louisville, Ky.; Dr. Allen Greenwood, Boston, and Dr. Kaspar Pischel, San Francisco.

To the Committee of National Museum of Ophthalmic Pathology (Joint), Dr. Jonas S. Friedenwald, Baltimore, was appointed.

To the Committee from the Section to cooperate with the National Committee for the Prevention of Blindness, the following were appointed: Dr. William H. Luedde, St. Louis, chairman; Dr. John W. Burke, Washington, D. C., and Dr. Delaware F. Harbridge, Phoenix, Ariz.

To the Committee on Standardization of Drugs and Instruments, the following were appointed: Dr. Clifford Walker, Los Angeles (one year); Dr. Francis H. Adler, Philadelphia (two years); Dr. Jonas S. Friedenwald, Baltimore (three years); Dr. Sanford R. Gifford, Chicago (four years), and Dr. Alfred Cowan, Philadelphia (five years).

Drs. Arnold Knapp, New York, Nelson M. Black, Miami, Fla., and Walter Parker, Detroit, were appointed to constitute the Knapp Medal Award Committee.

Dr. John Green, St. Louis, read the report on the Scientific Medal, and the medal was awarded to Dr. Phillips Thygeson of New York.

At the Demonstration Session the following were shown: Dr. Warren D. Horner, San Francisco, presented a device for removing adhesive plaster dressings.

Dr. Clifford B. Walker, Los Angeles, demonstrated a new electrical unit for separated retina work.

Dr. Otto Barkan, San Francisco, presented an operative procedure for the shallow chamber type of glaucoma.

Dr. K. C. Brandenburg, Long Beach, Calif., presented a flashing device for orthoptic training.

Dr. Walter H. Fink, Minneapolis, presented a depth perception apparatus.

Dr. Conrad Berens, New York, presented a prism scale.

Scientific Session

Dr. Trygve Gundersen, Boston, read a paper on "Vascular Obliteration for Various Types of Keratitis, with Special Reference to the Nutrition of Corneal Epithelium." Discussed by Drs. Albert D. Ruedemann, Cleveland; Charles A. Bahn, New Orleans, and Trygve Gundersen, Boston.

Dr. Theodore E. Sanders, St. Louis, read a paper on "Mixed Tumors of the Lacrimal Gland." Discussed by Drs. William L. Benedict, Rochester, Minn.; Georgiana Dvorak Theobald, Oak Park, Ill.; Howard C. Naffziger, San Francisco, and Theodore E. Sanders, St. Louis.

Dr. Harold F. Whalman, Los Angeles, read a paper on "Vernal Conjunctivitis." Discussed by Drs. M. N. Beigelman, Los Angeles; Albert N. Lemoine, Kansas City, Mo., and Harold F. Whalman, Los Angeles.

Dr. George S. Sharp, Pasadena, Calif., read a paper on "Treatment of Cancer of the Eyelids." Discussed by Drs. Everett L. Goar, Houston, Texas; Dohrmann K. Pischel, San Francisco, and Otis A. Sharpe, San Francisco.

SECTION ON LARYNGOLOGY, OTOTOLOGY AND RHINOLOGY

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Gordon B. New, Rochester, Minn.

Dr. Forrest J. Pinkerton, Honolulu, Hawaii, read a paper on "Leprosy of the Upper Respiratory Tract: Discussion of Early and Moderately Advanced Cases." Discussed by Drs. R. W. Burlingame, San Francisco; Ralph Fenton, Portland, Ore., and Forrest J. Pinkerton, Honolulu, Hawaii.

Dr. Austin A. Hayden, Chicago, read a paper on "Hearing Aids from Otologists' Audiograms."

Drs. Isaac H. Jones and Vern O. Knudsen, Los Angeles, presented a paper on "What Audiometry Can Now Mean in Routine Practice."

These two papers were discussed by Drs. William P. Wherry, Omaha; Horace Newhart, Minneapolis; Harold A. Fletcher, San Francisco; Howard A. Carter, Chicago; David Higbee, San Diego, Calif.; Austin A. Hayden, Chicago, and Isaac H. Jones, Los Angeles.

Dr. Edward J. Whalen, Hartford, Conn., read a paper on "Fungous Infections of the External Ear." Discussed by Drs. William D. Gill, San Antonio, Texas; Millard F. Arbuckle, St. Louis, and Edward J. Whalen, Hartford, Conn.

Dr. Bert E. Hempstead, Rochester, Minn., read a paper on "Osteomas of Paranasal Sinuses and the Mastoid Process, with a Report of Cases." Discussed by Drs. George H. Willcutt, San Rafael, Calif.; Thomas E. Carmody, Denver, and H. B. Graham, San Francisco.

THURSDAY, JUNE 16—AFTERNOON

Dr. Gordon B. New, Rochester, Minn., read the chairman's address, entitled "Benign Tumors of the Larynx: A Study of 722 Cases."

Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, presented a paper on "Cancer of the Larynx." Discussed by Drs. Max Cutler, Chicago; Simon Jesberg, Los Angeles; Joseph C. Beck, Chicago, and Chevalier L. Jackson, Philadelphia.

Dr. H. Marshall Taylor, Jacksonville, Fla., read a paper on "Chilling of the Body Surfaces and Its Relationship to Aural and Sinus Infection." Discussed by Drs. Edward Cecil Sewall,

San Francisco; John J. Shea, Memphis, Tenn.; Burt R. Shurly, Detroit, and H. Marshall Taylor, Jacksonville, Fla.

Dr. E. G. Galbraith, Toledo, Ohio, read a paper on "The Clinical Significance of Recent Work on Apneumohematosi." Discussed by Drs. J. Mackenzie Brown, Los Angeles, and E. G. Galbraith, Toledo, Ohio.

Dr. Frank R. Spencer, Boulder, Colo., read a paper on "Malignant Disease of the External Ear, with a Report of Eight Cases." Discussed by Drs. H. P. Mosher, Boston; Gordon B. New, Rochester, Minn.; Thomas E. Carmody, Denver, and Frank R. Spencer, Boulder, Colo.

Drs. Frank B. Kistner and Thomas D. Robertson, Portland, Ore., presented a paper on "Benign Granuloma of the Nose (So-Called Sarcoid): Report of a Case." Discussed by Drs. Matthew N. Hosmer, San Francisco, and Frederick T. Hill, Waterville, Maine.

FRIDAY, JUNE 17—AFTERNOON

Dr. Horace Newhart, Minneapolis, presented a portable booth for use in hearing tests and an audiometer.

Dr. Joseph C. Beck, Chicago, reported for the American Board on Otolaryngology that sixty-five men had taken the examination in this city.

In the absence of Dr. Chevalier Jackson, Dr. LeRoy A. Schall, Boston, read the report of the Committee on Lye Legislation, which was accepted.

The following officers were elected: chairman, Dr. H. Marshall Taylor, Jacksonville, Fla.; vice chairman, Dr. Harold A. Fletcher, San Francisco; secretary, Dr. LeRoy A. Schall, Boston.

Dr. William J. Mellinger, Santa Barbara, Calif., read a paper on "The Petrous Apex of the Temporal Bone and Its Relations." Discussed by Drs. J. Parsons Schaeffer, Philadelphia; Olof Larsell, Portland, Ore.; Henry J. Profant, Santa Barbara, Calif.; Louis K. Guggenheim, Los Angeles; Joseph C. Beck, Chicago, and William J. Mellinger, Santa Barbara, Calif.

Drs. Durwin H. Brownell and I. Jerome Hauser, Ann Arbor, Mich., presented a paper on "Malignancy of the Nasopharynx." Discussed by Drs. Joseph C. Beck, Chicago; John H. Childrey, San Francisco; Robert F. Ridpath, Philadelphia; James F. Percy, Los Angeles; Barney M. Kully, Los Angeles, and I. Jerome Hauser, Ann Arbor, Mich.

Dr. Herman Z. Semenov, Los Angeles, read a paper on "Surgical Pathology of Sinusitis." Discussed by Drs. Roy F. Nelson, Oakland, Calif.; Raymond O. Dart, San Francisco, and Herman Z. Semenov, Los Angeles.

Dr. David R. Higbee, San Diego, Calif., read a paper on "Cerebrospinal Rhinorrhea, with a Report of a Case Cured by Operation." Discussed by Drs. Howard C. Naffziger, San Francisco; Arthur C. Jones, Boise, Idaho, and David R. Higbee, San Diego, Calif.

Dr. C. Coulter Charlton, Atlantic City, N. J., read a paper on "Atrophic Rhinitis and Ozena at the Seashore: Further Observations." Discussed by Drs. Frank B. Kistner, Portland, Ore.; Robert F. Ridpath, Philadelphia, and C. Coulter Charlton, Atlantic City, N. J.

SECTION ON PEDIATRICS

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9:10 by the chairman, Dr. Clifford Sweet, Oakland, Calif.

Dr. Clifford Sweet, Oakland, Calif., read the chairman's address, entitled "Opportunities in Pediatric Practice."

Dr. Oswald H. Robertson, Chicago, read a paper on "Recent Studies on Experimental Lobar Pneumonia: Pathogenesis, Recovery and Immunity."

Dr. James A. Conner, Chicago, read a paper on "Treatment of Pertussis." Discussed by Drs. John M. Frawley, Fresno, Calif.; John J. Miller Jr., San Francisco; W. Ambrose McGee, Richmond, Va., and James A. Conner, Chicago.

Drs. Perrin H. Long and Eleanor A. Bliss, Baltimore, presented a paper on "Further Observations on the Mode of Action, the Clinical Use and the Toxic Manifestations of Sulfanilamide." Discussed by Drs. Francis Scott Smyth, San Francisco; Thomas B. Cooley, Detroit, and Perrin H. Long, Baltimore.

Dr. Henry F. Helmholtz, Rochester, Minn., read a paper on "Diagnosis and Treatment of Urinary Infections." Discussed by Dr. William P. Herbst, Washington, D. C.

Dr. Bret Ratner, New York, read a paper on "Onset and Natural Progress of Allergy in Childhood." Discussed by Drs. Milton B. Cohen, Cleveland, and Tell Nelson, Evanston, Ill.

THURSDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Radiology.

Dr. W. Walter Wasson, Denver, read a paper on "Nasal Accessory Sinus Disease: Its Beginning and Progress as Portrayed by the Roentgen Ray."

Dr. Edward Clay Mitchell, Memphis, Tenn., read a paper on "Sinus Treatment in Children."

Dr. Sidney N. Parkinson, Oakland, Calif., read a paper on "Ephedrine in a Physiologic Vehicle and Lateral Head-Low Posture in Treatment of the Nose and Sinuses."

These three papers were discussed by Drs. Thomas E. Carmody, Denver; John J. Shea, Memphis, Tenn.; Roy F. Nelson, Oakland, Calif.; Edward C. Sewall, San Francisco; Eric Ogden, Berkeley, Calif.; Clifford Sweet, Oakland, Calif.; W. Walter Wasson, Denver, and Sidney N. Parkinson, Oakland, Calif.

Drs. A. Graeme Mitchell and Josef Warkany, Cincinnati, presented a paper on "The Thymus Problem in Children."

Dr. Clyde K. Hasley, Detroit, read a paper on "Radiology's Responsibility in the Diagnosis and Treatment of Thymic Hyperplasia."

Drs. L. G. Rowntree and N. H. Einhorn, Philadelphia, presented a paper on "Experimental Phases of the Thymus Problem."

These three papers were discussed by Drs. W. Edward Chamberlain, Philadelphia; Edith Boyd, Minneapolis; Randolph G. Flood, San Francisco; Herbert E. Coe, Seattle; Henry F. Helmholtz, Rochester, Minn., and Clyde K. Hasley, Detroit.

The chairman appointed, as a resolutions committee, Drs. E. J. Barnett, Spokane, Wash., chairman, and E. Earl Moody, Los Angeles.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Dr. Edward Clay Mitchell, Memphis, Tenn.; vice chairman, Dr. Jean V. Cook, St. Louis, Mo.; secretary, Dr. Albert D. Kaiser, Rochester, N. Y.; delegate, Dr. William Weston, Columbia, S. C.; alternate, Dr. A. Graeme Mitchell, Cincinnati; representative to Scientific Exhibit, Dr. Arthur F. Abt, Chicago.

Dr. Horton R. Casparis, Nashville, Tenn., presented the report of the executive committee as follows:

Dr. Hugh L. Dwyer, Kansas City, Mo., reported to the executive committee that the amount at present in the Abraham Jacobi Memorial Fund is \$7,476.68; that from year to year the income from the fund has been used to help defray the expenses of guest speakers; that until recently members were called on to augment this fund by donating to it but that during the past year or two this was not done, and temporarily it is recommended that the policy be continued.

The executive committee recommended that Dr. Hugh L. Dwyer, Kansas City, Mo., be elected secretary-treasurer of the Abraham Jacobi fund for the next year.

On motion by Dr. William Weston, Columbia, S. C., duly seconded, Dr. Dwyer was elected for one year secretary-treasurer of the Abraham Jacobi Fund.

Dr. E. J. Barnett, Spokane, Wash., chairman of the resolutions committee, presented the report of that committee, as follows:

WHEREAS, The Section on Pediatrics of the American Medical Association has enjoyed an excellently arranged meeting through the efforts of the San Francisco pediatricians; and,

WHEREAS, The local pediatricians have also been royal hosts; and, WHEREAS, Each member of the section feels it is a privilege to have attended this meeting of 1938 and looks forward to an early return to this hospitable, friendly city; therefore, be it

Resolved, That the Section on Pediatrics here assembled extend its thanks and appreciation to our friends, the pediatricians of San Francisco.

E. J. BARNETT.
E. EARL MOODY.

On motion of Dr. William Weston, Columbia, S. C., duly seconded, the report was unanimously adopted.

Dr. Henry F. Helmholtz, Rochester, Minn., reported that he had extended the invitation of the section to the International Congress in Rome last fall; that the next International Congress will meet in Boston, Sept. 9, 10 and 11, 1940, and urged all who could to attend.

Dr. William Weston, Columbia, S. C., delegate to the House, addressed the section.

It was suggested by the chairman that the matter of program for next year be left to the executive committee and the secretary, with the understanding that if it seems feasible to work out a suitable panel discussion next year the section has no objection to it.

Drs. Julian D. Boyd and Robert L. Jackson, Iowa City, presented a paper on "Levels of Control in the Treatment of Diabetes Mellitus." Discussed by Drs. Percival A. Gray Jr., Santa Barbara, Calif.; Leona M. Bayer, San Francisco, and Julian D. Boyd, Iowa City.

Dr. Mandel L. Spivek, Chicago, read a paper on "A Consideration of Present Day Newborn Nursery Practice and Suggestions for Improvement." Discussed by Drs. Ernest Wolff, San Francisco; L. Howard Smith, Portland, Ore.; Maurice L. Blatt, Chicago; M. K. Wylder, Albuquerque, N. M.; Irving J. Wolman, Philadelphia, and Mandel L. Spivek, Chicago.

Dr. Horton R. Casparis, Nashville, Tenn., read a paper on "Should the Tuberculosis Problem in Children be the Responsibility of the Health Officer or the Pediatrician?" Discussed by Drs. V. W. Spickard, Seattle; M. K. Wylder, Albuquerque, N. M.; Henry F. Helmholtz, Rochester, Minn.; Ernest Wolff, San Francisco, and Horton R. Casparis, Nashville.

Dr. W. Ambrose McGee, Richmond, Va., read a paper on "Allergy of Childhood: Prophylaxis, Early Recognition and Treatment." Discussed by Drs. George Piness, Los Angeles; Margaret M. Nicholson, Washington, D. C.; Julian Cohn, Los Angeles, and W. Ambrose McGee, Richmond.

Dr. Katsuji Kato, Chicago, read a paper on "Hematologic Indexes in Normal and Anemic Infants and Children: A Triaxial Graphic Method." Discussed by Drs. Russell L. Haden, Cleveland, and Katsuji Kato, Chicago.

Dr. Orville E. Barbour, Peoria, Ill., read a paper on "Certain Therapeutic Effects of Whole Adrenal Gland by Mouth." Discussed by Drs. E. Kost Shelton, Los Angeles; Hans Lisser, San Francisco; Mandel L. Spivek, Chicago, and Orville E. Barbour, Peoria.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. Russell L. Haden, Cleveland.

Dr. Samuel S. Altschuler, Detroit, read a paper on "The Use of Crystalline Insulin in the Treatment of Patients with Severe Diabetes."

Drs. Percival Allen Gray Jr., Fritz Emil Bischoff and W. D. Sansum, Santa Barbara, Calif., presented a paper on "Histone Insulin and Allied Insulin Compounds."

These two papers were discussed by Drs. H. Clare Shepardson, San Francisco; Roger Holcomb, Portland, Ore.; A. A. Herold, Shreveport, La.; Lester J. Palmer, Seattle; Samuel S. Altschuler, Detroit, and Percival Allen Gray Jr., Santa Barbara, Calif.

A motion was carried to send a message of regret to Dr. Irving S. Wright, New York, secretary, ill for the past two months. Dr. Erwin E. Nelson, New Orleans, vice chairman, acted in his stead.

Drs. Tom Douglas Spies and William B. Bean, Cincinnati, and Robert E. Stone, Birmingham, Ala., presented a paper on "The Treatment of Pellagra by Means of Nicotinic Acid." Discussed by Drs. Thomas T. Mackie, New York; Julian M. Ruffin, Durham, N. C.; Mohammed Abdo Abbasy, Cairo, Egypt; J. N. Baker, Montgomery, Ala.; James E. Paullin, Atlanta, Ga.; A. J. Carlson, Chicago; P. J. Hanzlik, San Francisco; William De Kleine, American Red Cross, and Tom Douglas Spies, Cincinnati.

Dr. Gordon A. Alles, Los Angeles, read a paper on "Drugs Acting on the Autonomic Nervous System: Phenyl and Sub-

stituted Phenyl Alkylamines." Discussed by Drs. Clinton H. Thienes, Los Angeles; M. H. Nathanson, Los Angeles; P. J. Hanzlik, San Francisco, and Gordon A. Alles, Los Angeles.

Dr. M. L. Tainter, San Francisco, read a paper on "The Choice of a Sympathetic Stimulant for Treating Abnormal Circulatory States." Discussed by Drs. David A. Ryland, San Francisco; E. Geiger, Budapest Hungary; Gordon A. Alles, Los Angeles, and M. H. Nathanson, Los Angeles.

Drs. George P. Robb and Israel Steinberg, New York, presented a paper on "Visualization of the Pulmonary Circulation in Man by Means of Peripheral Intravenous Injection." Discussed by Drs. Edgar V. Allen, Rochester, Minn., and George P. Robb, New York.

THURSDAY, JUNE 16—MORNING

Dr. Russell L. Haden, Cleveland, read the chairman's address, entitled "Historical Aspects of the Use of Iron and Liver in the Treatment of Anemia."

The following papers were read as a symposium on "Blood Dyscrasias":

Dr. Edwin E. Osgood, Portland, Ore.: "The Culture of Human Marrow as an Aid in the Evaluation of Therapeutic Agents."

Dr. Harold W. Jones, Philadelphia: "The Treatment of Pathologic Hemorrhage."

Dr. Nathan Rosenthal, New York: "The Treatment of Thrombocytopenic Purpura Haemorrhagica."

Dr. William P. Murphy, Boston: "The Treatment of Pernicious Anemia."

Drs. W. M. Fowler and Adelaide P. Barer, Iowa City: "The Treatment of Iron Deficiency Anemias."

These five papers were discussed by Drs. L. W. Diggs, Memphis, Tenn.; F. W. Madison, Milwaukee; Frank J. Heck, Rochester, Minn.; Frank Nuzum, Santa Barbara; Edwin E. Osgood, Portland, Ore.; Harold W. Jones, Philadelphia; Nathan Rosenthal, New York; William P. Murphy, Boston, and W. M. Fowler, Iowa City.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Dr. Erwin E. Nelson, New Orleans; vice chairman, Dr. Irving S. Wright, New York; secretary, Dr. Edgar V. Allen, Rochester, Minn.; council: Drs. Cary Eggleston, New York, and Russell L. Haden, Cleveland.

Dr. M. Herbert Barker, Chicago, read a paper on "Sodium Chloride Tolerance in Chronic Nephritis, with Some Observations on Potassium and Sulfate Ions." Discussed by Drs. Thomas Addis, San Francisco; William Dock, San Francisco; A. A. Herold, Shreveport, La., and M. Herbert Barker, Chicago.

Dr. Herbert O. Calvery, Washington, D. C., read a paper on "Chronic Effects of Ingested Lead and Arsenic." Discussed by Drs. Floyd DeEds, San Francisco; Erwin E. Nelson, New Orleans, and P. J. Hanzlik, San Francisco.

Drs. S. R. Mettler and Chauncey D. Leake, San Francisco, presented a paper on "The Evaluation of Drugs Commonly Employed as Diagnostic Aids in Clinical Medicine." Discussed by Drs. Frank R. Nuzum, Santa Barbara, Calif., and Russell L. Haden, Cleveland.

Dr. Norman H. Plummer, New York, read a paper on "The Use of Serum in the Higher Types of Pneumonia." Discussed by Drs. Edward L. Bortz, Philadelphia; Byron F. Francis, Seattle; Philip G. Corliss, Somerton, Ariz.; William C. Bruff, Whittier, Calif., and Norman H. Plummer, New York.

Dr. F. M. Pottenger Sr., Monrovia, Calif., read a paper on "The Use of Adrenal Hormones in the Treatment of Asthenia, Asthma and Tuberculosis." No discussion.

Drs. E. G. Bannick, A. E. Brown and F. P. Foster, Rochester, Minn., presented a paper entitled "Further Clinical Observations on Therapeutic Effectiveness and Toxicity of Sulfanilamide and Several Related Compounds." Discussed by Drs. Dwight L. Wilbur, San Francisco; Edwin E. Osgood, Portland, Ore.; Russell L. Haden, Cleveland, and E. G. Bannick, Rochester, Minn.

SECTION ON PATHOLOGY AND
PHYSIOLOGY

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Roy R. Kracke, Emory University, Ga.

The "Report on the Council on Medical Education and Hospitals to the House of Delegates of the American Medical Association" was read by the chairman.

The following applicants for Associate Fellowship were nominated: Benjamin J. Clawson, M.D., Minneapolis; Joseph Erlanger, M.D., St. Louis; John P. Quigley, M.D., Cleveland; William C. Rose, Ph.D., Urbana, Ill.

A nominating committee was appointed, consisting of Drs. F. H. Lamb, Davenport, Iowa, chairman; Thomas B. Magath, Rochester, Minn., and Alvin G. Foord, Pasadena, Calif.

Dr. R. A. Bartholomew, Atlanta, Ga., read a paper on "Pathology of the Placenta, with Particular Reference to Infarcts and Their Relation to the Toxemias of Pregnancy." Discussed by Drs. A. J. Carlson, Chicago; Roy R. Kracke, Emory University, Ga.; Frank W. Hartman, Detroit, and R. A. Bartholomew, Atlanta, Ga.

Dr. Edwin F. Hirsch, Chicago, read a paper on "Arterial Occlusions with Aseptic Necrosis of Bones." No discussion.

Dr. H. E. Robertson, Rochester, Minn., read a paper on "The Etiology and Pathogenesis of Alcoholic Cirrhosis of the Liver." Discussed by Drs. Ernest M. Hall, Los Angeles; Frank R. Menne, Portland, Ore.; A. J. Carlson, Chicago, and Charles L. Connor, San Francisco.

Dr. Meyer Bodansky, Galveston, Texas, read a paper on "Regulation of the Serum Calcium Level During Pregnancy." No discussion.

Drs. Frank W. Hartman and Victor Schelling, Detroit, presented a paper entitled "Studies on Hexyl Chloro-m-Cresol and Other Carbocyclic Antiseptics." No discussion.

Dr. Samuel M. Feinberg, Chicago, and O. C. Durham, North Chicago, Ill., presented a paper on "Annual Variations in Seasonal Aspects of Mold Allergy: A Clinical and Atmospheric Study of Over Three Years." Discussed by Drs. J. H. Black, Dallas, Texas, and F. W. Wittich, Minneapolis, and O. C. Durham, North Chicago, Ill.

THURSDAY, JUNE 16—AFTERNOON

Dr. Roy R. Kracke, Emory University, Ga., read the chairman's address, entitled "Relation of Drug Therapy to Neutropenic States."

The following papers were read as a symposium on "Blood Dyscrasias":

Drs. E. M. Butt and A. M. Hoffman, Los Angeles: "Agranulocytosis Produced Experimentally in Dogs by the Feeding of Aminopyrine." No discussion.

Drs. Frank J. Heck and Byron E. Hall, Rochester, Minn.: "Leukemoid Reactions." Discussed by Drs. Harry A. Wyckoff, San Francisco; Nathan Rosenthal, New York, and Frank J. Heck, Rochester, Minn.

Dr. Joseph M. Hill, Dallas, Texas: "Red Cell Dimensions in Familial Hemolytic Anemia with Particular Reference to Atypical Cases." Discussed by Drs. Russell L. Haden, Cleveland; M. C. Riddle, Portland, Ore., and Joseph M. Hill, Dallas.

Dr. L. W. Diggs, Memphis, Tenn.: "The Erythrocyte in Sick Cell Anemia." Discussed by Drs. Edwin E. Osgood, Portland, Ore., and L. W. Diggs, Memphis, Tenn.

Dr. Israel Davidsohn, Chicago: "A Method of Differentiation of Blood Groups A₁ and A₂." Discussed by Drs. Harry Rosenthal, New York; Alvin G. Foord, Los Angeles, and Israel Davidsohn, Chicago.

Dr. James B. McNaught, San Francisco: "The Gordon Test for Hodgkin's Disease: A Reaction to Eosinophils." No discussion.

FRIDAY, JUNE 17—AFTERNOON

The following officers were elected: chairman, Dr. Maurice B. Visscher, Minneapolis; vice chairman, Dr. Frank W. Hartman, Detroit; secretary, Dr. J. J. Moore, Chicago; delegate, Dr. L. W. Larson, Bismarck, N. D.; alternate, Dr. J. J. Moore, Chicago; nominee to American Board of Pathology, Dr. Howard T. Karsner, Cleveland.

Dr. Philip B. Matz, Washington, D. C., read a paper on "Incidence of Primary Bronchiogenic Carcinoma." Discussed by Dr. Max Cutler, Chicago.

Drs. Alvin G. Foord and Paul A. Ferrier, Pasadena, Calif., presented a paper on "Primary Carcinoma of the Ureter." No discussion.

Drs. Harry C. Schmeisser and W. A. D. Anderson, Memphis, Tenn., presented a paper on "Solid Ovarian Tumors." Discussed by Drs. Alvin G. Foord, Pasadena, Calif.; Alfred S. Giordano, South Bend, Ind.; Elmer W. Smith, San Francisco, and Harry C. Schmeisser, Memphis, Tenn.

Dr. Robert C. Page, Tuckahoe, N. Y., read a paper on "Cytology of the Skin of Mice During Application of Carcinogenic Agents, Methylcholanthrene and Cholanthrene." Discussed by Drs. Philip B. Matz, Washington, D. C., and Robert C. Page, Tuckahoe, N. Y.

Drs. Henry C. Sweany and Rosalind Klaas, Chicago, presented a paper on "X-Ray Diffraction Analysis as Applied in Pneumoconiosis." No discussion.

Drs. Harry J. Corper and Maurice L. Cohn, Denver, presented a paper on "The Effects of Tuberculo-protein: A Quantitative Study." No discussion.

SECTION ON NERVOUS AND MENTAL
DISEASES

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9:15 by the chairman, Dr. Samuel D. Ingham, Los Angeles.

The following resolution was presented to the section by Dr. Tom B. Throckmorton, Des Moines, Iowa, as coming from Dr. Foster Kennedy, New York:

WHEREAS, State and federal legislation governing the control of reproduction is conflicting and renders certain phases of medical practice illegal, it is important that the profession of medicine as a whole should clarify and lead in these questions involving medical practice and procedures. The importance of such control in medical practice where such control constitutes a therapeutic measure is obvious to enlightened lay opinion throughout the civilized world and should be obvious to all medical men not mediocrally minded; therefore be it

Resolved, That we hereby recommend the alteration of existing laws wherever necessary, so that physicians may legally give contraceptive information to their patients; and be it further

Resolved, That we recommend an amendment to sections 211, 245, 311 and 312 of the Federal Penal Code as follows: "Standard medical and scientific journals and reprints therefrom and standard medical works which contain information regarding the prevention of conception are not nonmailable under this section"; and be it further

Resolved, That a full and frank discussion be given in regard to these subjects by a proper deliberative council of the American Medical Association.

On motion regularly made and seconded, the foregoing resolution was approved, to be transmitted to the House of Delegates.

Drs. L. H. Ziegler, Wauwatosa, Wis., and C. P. Sheldon, Boston, presented a paper on "Marriage Among the Mentally Retarded." Discussed by Drs. Dwight L. Wilbur, San Francisco; Lawrence Kolb, Lexington, Ky.; Fred O. Butler, Eldridge, Calif., and L. H. Ziegler, Wauwatosa, Wis.

Dr. Robert P. Knight, Topeka, Kan., read a paper on "The Psychoanalytic Treatment of Chronic Alcoholic Addiction in a Sanatorium." Discussed by Drs. F. G. Ebaugh, Denver; Karl A. Menninger, Topeka, Kan.; Edward J. Mayer, Pittsburgh; Herman S. Major, Kansas City, Mo., and Robert P. Knight, Topeka, Kan.

Dr. Samuel D. Ingham, Los Angeles, read the chairman's address, entitled "Some Neurologic Aspects of Psychiatry."

Dr. Richard M. Brickner, New York, read a paper on "A Follow-Up Report of a Human Being with Bilateral Frontal Lobectomy: Comparison with Cases of Unilateral Lobectomy." Discussed by Drs. W. F. Schaller, San Francisco; J. M. Nielsen, Los Angeles; Walter Freeman, Washington, D. C.; L. H. Ziegler, Wauwatosa, Wis., and Richard M. Brickner, New York.

Dr. Hans H. F. Reese, Madison, Wis., read a paper on "Clinical Observations and Results with Hypoglycemia and Convulsive Therapy in Schizophrenia."

Drs. Richard H. Young and G. Alexander Young, Omaha, presented a paper on "Treatment of the Psychoses with Hypoglycemia and Induced Convulsions."

These two papers were discussed by Drs. A. A. Low, Chicago; Titus H. Harris, Galveston, Texas; A. E. Bennett, Omaha; Emerick Friedman, Greenwich, Conn.; George W. Hall, Chicago; Eugene Ziskind, Los Angeles; Harold E. Himwich, Albany, N. Y., and Hans H. F. Reese, Madison, Wis.

THURSDAY, JUNE 16—MORNING

Drs. Olof Larsell and Robert S. Dow, Portland, Ore., presented a paper on "The Cerebellum: A New Interpretation." Discussed by Drs. Frederick L. Reichert, San Francisco; Webb E. Haymaker, San Francisco, and Olof Larsell, Portland, Ore.

Dr. K. G. McKenzie, Toronto, Canada, read a paper on "The Present Status of a Patient Who Has Had the Right Cerebral Hemisphere Removed." Discussed by Drs. Max M. Peet, Ann Arbor, Mich.; Henry R. Viets, Boston; Richard M. Brickner, New York; Paul C. Bucy, Chicago; Walter Freeman, Washington, D. C.; A. L. Skoog, Kansas City, Mo., and K. G. McKenzie, Toronto, Canada.

Dr. W. J. Gardner, Cleveland, read a paper on "Cerebral Pseudo-Tumor and Pseudo-Abscess." Discussed by Drs. Harry Wilkins, Oklahoma City; R. B. Raney, Los Angeles; Max M. Peet, Ann Arbor, Mich.; J. M. Nielson, Los Angeles; George W. Hall, Chicago; O. W. Jones Jr., San Francisco, and W. J. Gardner, Cleveland.

Dr. R. E. Semmes, Memphis, Tenn., read a paper on "Intracranial Arteriovenous Varices with Brief Report of Ten Cases of Different Types and Special Reference to Treatment by Ligation." Discussed by Drs. Hale A. Haven, Seattle; E. B. Towne, San Francisco, and R. E. Semmes, Memphis, Tenn.

Drs. W. McK. Craig and J. W. Kernohan, Rochester, Minn., presented a paper on "Tumors of the Fourth Ventricle."

Drs. D. N. Buchanan and Percival Bailey, Chicago, presented a paper on "Brain Tumors in Infancy and Childhood."

These two papers were discussed by Drs. F. R. Teachenor, Kansas City, Mo.; Delbert H. Werden, San Diego, Calif.; Francis C. Grant, Philadelphia; W. McK. Craig, Rochester, Minn., and D. N. Buchanan, Chicago.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Francis C. Grant, Philadelphia; vice chairman, Richard M. Brickner, New York; secretary, Paul C. Bucy, Chicago; executive committee: Henry R. Viets, Boston; Samuel D. Ingham, Los Angeles, and Francis C. Grant, Philadelphia; delegate, Tom B. Throckmorton, Des Moines, Iowa; alternate, Edward J. Delehanty, Denver; representative on American Board of Psychiatry and Neurology, Titus H. Harris, Galveston, Texas; representative to Scientific Exhibit, Roland P. Mackay, Chicago.

Dr. Tom B. Throckmorton, Des Moines, Iowa, delegate to the House, made a report on the session of the House of Delegates, which was accepted.

It was voted that a letter of congratulations be sent to Dr. Rock Sleyster, Wauwatosa, Wis., President-Elect.

Dr. A. E. Bennett, Omaha, read a paper on "Horse Serum Neuritis." Discussed by Drs. Foster Kennedy, New York; Walter Freeman, Washington, D. C.; John B. Doyle, Los Angeles; Hyman I. Vener, Los Angeles; Henry R. Viets, Boston; Tom B. Throckmorton, Des Moines, Iowa; Leopold Brahdy, New York; L. H. Ziegler, Wauwatosa, Wis., and A. E. Bennett, Omaha.

Dr. Josephine B. Neal, New York, read a paper on "The Treatment of Acute Infections of the Central Nervous System with Sulfanilamide." Discussed by Drs. R. Cannon Eley, Boston; Henry W. Woltman, Rochester, Minn., and Josephine B. Neal, New York.

Dr. R. P. Mackay, Chicago, read a paper on "Chronic Adhesive Spinal Arachnoiditis: A Clinical and Pathologic Study." Discussed by Drs. John B. Doyle, Los Angeles; J. M. Nielsen, Los Angeles, and R. P. Mackay, Chicago.

Drs. H. H. Merriitt and T. J. Putnam, Boston, presented a paper on "Clinical Experiences with Diphenylhydantoin: A New Anticonvulsant Drug." Discussed by Drs. Eugene Ziskind, Los Angeles; Burt R. Shurly, Detroit, and T. J. Putnam, Boston.

Dr. William J. German Jr., New Haven, Conn., read a paper on "Results of Removal of Cerebral Cortical Scars."

Drs. Leonard T. Furlow and Ernest Sachs, St. Louis, presented a paper on "Subpial Resection of the Cerebral Cortex for Focal Epilepsy: Further Observations."

These two papers were discussed by Drs. R. Glen Spurling, Louisville, Ky.; William J. German Jr., New Haven, Conn., and Leonard T. Furlow, St. Louis.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. Joseph V. Klauder, Philadelphia.

Dr. Howard Fox, New York, read the report of the Committee on American Academy of Dermatology and Syphilology: "At the last meeting of this section on June 11, 1937, the chairman, Dr. O'Leary, appointed a committee of seven with myself as chairman to study the formation of an American Academy of Dermatology and Syphilology. The committee met in Chicago on Sept. 10, 1937, a time that was also chosen for the meeting of the organizing committee of the International Congress. This offered an unusual opportunity for a large group of dermatologists representing all parts of the country to meet and discuss the proposed American Academy. Accordingly, with the consent of Dr. O'Leary, the committee was enlarged to include the members of the congress committee, making a total of seventeen. A meeting of this enlarged committee was held and it was unanimously agreed that the proposed academy should be formed in the near future.

"The meeting of the Central States Dermatological Society in Detroit on January 14 afforded an opportunity for a large number of dermatologists to get together and form the new academy. At this meeting, which was attended by 300 dermatologists, a constitution was adopted and the American Academy of Dermatology and Syphilology was organized. Further details of this inaugural meeting have been published in the *Archives of Dermatology and Syphilology* and in *The Journal of the American Medical Association*."

Dr. Oliver S. Ormsby, Chicago, reported that the joint committee of the American Dermatological Association and the Section on Dermatology and Syphilology of the American Medical Association to make preparations for the International Congress on Dermatology and Syphilology had organized and elected Dr. Paul A. O'Leary, Rochester, Minn., secretary general. Dr. O'Leary supplemented the report with an outline of the plans for the congress to be held Sept. 9, 1940, at the Waldorf-Astoria in New York. Dr. Elmore B. Tauber, Cincinnati, further amplified the report with respect to the arrangements for financing the congress.

Dr. C. Guy Lane, Boston, read the following report of the American Board of Dermatology and Syphilology: "At the examination of the board last year in Philadelphia ninety-five applicants for certificates were considered; seventy-seven were examined (twelve of these for reexamination); fifty-one passed, twelve failed and fourteen were conditioned in one or more subjects. Certificates were awarded to the fifty-one candidates who completed the examination satisfactorily, so that diplomates of the board now number 383. During the past year a new booklet of information has been issued, a booklet on opportunities for graduate training has been revised and published, and a new issue of the Registry prepared, with both alphabetical and geographic sections. The syllabus is still in the process of revision. In February there was a meeting of the Advisory Board for Medical Specialties in which representatives of this board participated. Representatives of the twelve boards already formed, and other agencies interested in graduate medical education, discussed numerous questions. Among the most important were the following: (1) Further boards will probably be made subsidiaries of one of the existing boards; (2) a Commission on Graduate Medical Education has been formed and funds obtained for a three year study of educational facilities for graduate medical study; (3) the question of certification by more than one board was discussed, but the Advisory Board opposed multiple certification; (4) the assessment for the various participating bodies was reduced; (5) effective date of special training requirements was advanced to

Jan. 1, 1942. The authorities of the American Medical Association protest very strongly against the meeting of the various boards at the time of the A. M. A. meeting, so that it seems probable that the time of the board examination will be changed to coincide with the meeting of the new American Academy of Dermatology and Syphilology. It also seems probable that representation of the academy on the board should be arranged."

Dr. Harry R. Foerster, Milwaukee, chairman of the nominating committee, offered for the committee the name of Dr. Charles C. Dennie, Kansas City, Mo., to succeed himself on the American Board of Dermatology and Syphilology. The nomination was seconded and Dr. Dennie was unanimously elected.

Dr. Stefan Rothman, Budapest, Hungary, was presented by the chairman and invited to participate in the discussions.

Dr. Howard Fox, New York, presented the following report with regard to the *Archives of Dermatology and Syphilology*: "I want to thank the members of the section for their very kind cooperation in my efforts to run the *Archives* as well as I could, and I am also indebted to the other members of the editorial board for reviewing certain very technical articles. The Transactions, as Dr. Pusey used to say, constitute the most difficult problems of the *Archives*, and I certainly feel that way myself. There has been, I am glad to say, considerable improvement recently in the Transactions, largely due to the work of either the secretaries or small editorial boards that have been appointed by the individual societies, but with the improvement in the substance of the Transactions there has been unfortunately a delay and they have been slower than usual in reaching my office. I hope that you will do all you can in the future to speed up these Transactions, because otherwise I expect to spend the entire summer correcting them. It is going to be possible in the future to have photographic illustrations of cases and histopathologic cuts in the Transactions. I think that will greatly increase the value of the Transactions. In the preparation of manuscripts I would certainly urge every author, whether he writes an elaborate paper or merely reports a case in one of the societies, to become familiar with the book known as Medical Writing, by Dr. Fishbein. It contains certain rules and regulations that seem arbitrary but really are not so, and it contains a lot of valuable information about the preparation of manuscripts which will help you greatly, and I am sure if you follow these suggestions it will help the editor."

As chairman of the Advisory Committee on Syphilis Control, Dr. Paul A. O'Leary, Rochester, Minn., read the following letter from Dr. Thomas Parran, Surgeon General, United States Public Health Service, dated May 17, 1938:

I have learned from several sources that some of the dermatosyphilologists of the United States are of the opinion that the Public Health Service intends to utilize the services of specialists in internal medicine and other specialists in the field of medicine to the exclusion of dermatologists in the present campaign against syphilis. There is no intention to divorce syphilology from dermatology.

The syphilis problem in the United States is an enormous one, and I can assure you that the services of both dermatosyphilologists and internists will be required. Indeed, so prevalent is syphilis that it is my opinion that the aid of all general practitioners will be needed in addition to the special assistance of experts in the field.

The action of your committee in endorsing the campaign to control syphilis about a year ago was most encouraging. I hope that it will be possible to depend on you and the members of your Association in the prosecution of this important work in the future.

Dr. Joseph V. Klauder, Philadelphia, read the chairman's address, entitled "Erysipeloid as an Occupational Disease."

The following papers were read as a symposium on "Occupational Dermatoses":

Dr. C. Guy Lane, Boston: "Occupational Dermatoses: An Educational Program."

Dr. Louis Schwartz, New York: "The Incidence of Occupational Dermatoses and Their Causes in the Basic Industries."

Drs. Marion B. Sulzberger, New York, and Clark W. Finnerud, Chicago: "Industrial Dermatoses: Remarks on Criteria for Diagnosis."

Drs. Earl D. Osborne and James W. Jordon, Buffalo: "The Practical Aspect of the Prevention of Industrial Dermatoses."

Dr. John G. Downing, Boston: "Analysis of Claims in Industrial Dermatoses."

Dr. Harry R. Foerster, Milwaukee: "The Compensation Laws and Related Medicolegal Considerations of Industrial Dermatoses."

These six papers were discussed by Drs. Charles C. Dennie, Kansas City, Mo.; Cleveland J. White, Chicago; Hiram E. Miller, San Francisco; Stefan Rothman, Budapest, Hungary; J. Harper Blaisdell, Boston; Howard J. Parkhurst, Toledo, Ohio; Elmore B. Tauber, Cincinnati; Joseph V. Klauder, Philadelphia; M. T.-R. Maynard, San Jose, Calif.; Joseph Grindon, St. Louis; Eugene F. Traub, New York; C. Guy Lane, Boston; Louis Schwartz, New York; Clark W. Finnerud, Chicago; Earl D. Osborne, Buffalo; John G. Downing, Boston, and Harry R. Foerster, Milwaukee.

It was voted, on motion of Dr. Elmore B. Tauber, Cincinnati, that the papers in this symposium be published as a group.

THURSDAY, JUNE 16—MORNING

Dr. Clark W. Finnerud, Chicago, chairman of the Committee on Scientific Exhibit, presented the report of the committee as follows:

Dr. Fishbein tells me that it has come to his attention repeatedly in recent years that many individuals come to the annual meeting not to attend the scientific section meetings but to spend their full time in the Scientific Exhibit. He feels, as do most of the other officers, that it is really the most important part of the annual meeting. In our section, which was so ably built up by Dr. Weidman, things which he adopted have been copied by the various sections. This year our exhibit has been largely a practical one. We are handicapped by the fact that we are so far from the East this year, although the California exhibits have been exceptionally fine; we have been limited for space and have had to cut down considerably on the number of exhibits, and those who have been given space had to cut down to a minimum; our exhibit is not so neat as usual, but I think you will agree that any one who is willing to spend two or three hours there will find a world of instruction available, particularly in the industrial dermatoses portion, although everything else is very well illustrated. From the standpoint of instruction we really feel this year's exhibit has been very much worth while.

I presume you all feel, as I do, that the section should go along as in past years with this phase of the activities.

Dr. Downing said yesterday that the finest way to learn about any subject is to put on an exhibit in it or to prepare a paper on it. Dr. O'Leary remarked that a tremendous amount of interest centers around the exhibits illustrated with slides and particularly colored slides, and more especially colored motion pictures. I would predict that in the future there will tend to be more and more exhibits of that nature.

Our bank account is in a thoroughly healthy state owing to some financial aid annually, about \$25 a year, from the American Medical Association. We have a balance of \$88.76, which is, I think, approximately \$58 less than was turned over to me by Dr. Weidman in 1935.

The chairman appointed Drs. Harold N. Cole, Cleveland, Elmore B. Tauber, Cincinnati, and Howard Fox, New York, a committee to audit the books of the Committee on Scientific Exhibit.

The chairman called for reports from the Committees on Cosmetics and Industrial Dermatoses. There were no reports from these committees.

Dr. Earl D. Osborne, Buffalo, announced the dates of the meeting of the Academy of Dermatology and Syphilology as Nov. 14-15, 1938, at the Jefferson Hotel, St. Louis, and outlined the program.

Dr. Earl D. Osborne, Buffalo, as the section representative on the Council on Industrial Health of the American Medical Association, urged the members to answer questionnaires and to cooperate with the Council in its endeavor to formulate a compendium of industrial conditions.

Dr. C. Guy Lane, Boston, presented the following report of the Committee on Industrial Dermatoses:

At the meeting last year it was announced that the Council on Industrial Health had been authorized by the Trustees of the Association. This Council has been appointed and has organized. Dr. Earl D. Osborne has been appointed as the

representative of dermatology and has been active in this organization. A broad program has been outlined, and with the resources of the A. M. A. it is possible to see great progress in this subject in the next few years. The recommendation of this committee for a symposium has been carried out in this section and at the American Dermatological Association meeting, and an attempt will be made to have these papers published together as a separate monograph or perhaps as a supplement to the *Archives*. The matter of definitions and criteria are of major importance and will be carefully considered by this committee with a view to making a report to the section next year.

For the future the committee plans to cooperate with the new Council on Industrial Health in every possible way and to continue the development of subcommittees interested in this phase of Dermatology.

C. GUY LANE.
HARRY R. FOERSTER.
JOHN G. DOWNING.
CHARLES C. DENNIE.
MARION B. SULZBERGER.

Dr. Harold N. Cole, Cleveland, reported that the auditing committee had examined the books of the Committee on Scientific Exhibit and found them in order.

Dr. Reuben L. Kahn, Ann Arbor, Mich., read a paper entitled "Are There Paradoxical Serum Reactions in Syphilis?" Discussed by Drs. Frederick G. Novy Jr., Oakland, Calif.; Paul A. O'Leary, Rochester, Minn.; Stefan Rothman, Budapest, Hungary; William H. Goeckerman, Los Angeles; Harry M. Robinson Sr., Baltimore; Joseph V. Klauder, Philadelphia, and Reuben L. Kahn, Ann Arbor, Mich.

Drs. Donald M. Pillsbury and H. Harris Perlman, Philadelphia, presented a paper on "Acetarsone Therapy in 187 Cases of Prenatal Syphilis."

Drs. Harry M. Robinson and Harry M. Robinson Jr., Baltimore, presented a paper on "Acetarsone Orally in the Treatment of Acquired Syphilis in Adults."

These two papers were discussed by Drs. Harold N. Cole, Cleveland; Charles C. Dennie, Kansas City, Mo.; George V. Kulchar, San Francisco; W. Ray Jones, Seattle; Donald M. Pillsbury, Philadelphia, and Harry M. Robinson, Baltimore.

Drs. Torald H. Sollmann, Harold N. Cole, Katharine I. Henderson, Garrett A. Cooper, W. R. Love and W. F. Schwartz, Cleveland, presented a paper on "Combination Courses of Bismuth Administration." Discussed by Drs. George V. Kulchar, San Francisco; P. J. Hanzlik, San Francisco; Ben A. Newman, Los Angeles; Joseph Grindon, St. Louis; Harry M. Robinson, Baltimore; Elmore B. Tauber, Cincinnati, and Harold N. Cole, Cleveland.

Dr. Samuel Goldblatt, Cincinnati, read a paper on "Neurosyphilis in the Negro: Spinal Fluid Manifestations in Untreated and Treated Cases." Discussed by Drs. Marque O. Nelson, Tulsa, Okla.; Edward L. Merritt, Fall River, Mass.; Arthur A. Herold, Shreveport, La., and Samuel Goldblatt, Cincinnati.

Drs. Paul A. O'Leary, Rochester, Minn., Harold N. Cole, Cleveland, Joseph Earle Moore, Baltimore, John H. Stokes, Philadelphia, Udo J. Wile, Ann Arbor, Mich., Thomas Parran, R. A. Vonderlehr and Lida J. Usilton, Washington, D. C., presented a paper on "Tabes Dorsalis: Cooperative Clinical Studies in the Treatment of Syphilis." Discussed by Dr. Stefan Rothman, Budapest, Hungary.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Bedford Shelmire, Dallas, Texas; vice chairman, Robert C. Jamieson, Detroit; secretary, C. F. Lehmann, San Antonio, Texas; delegate, Clyde Cumber, Cleveland; alternate, Harold N. Cole, Cleveland; Scientific Exhibit Committee chairman, Hamilton Montgomery, Rochester, Minn.; Charles C. Dennie, Kansas City, Mo., American Board of Dermatology and Syphilology (elected Wednesday).

It was voted to send a message to Dr. Howard Morrow, San Francisco, regretting his absence, wishing him a speedy recovery, and congratulating him on his election as Vice President of the American Medical Association.

The chairman conveyed to the members for Dr. Schwartz his appreciation for their cooperation in the exhibit, which received the certificate, and his request for their continued support.

Dr. Henry A. Brunsting, Toledo, Ohio, read a paper on "Hidrosadenitis Suppurativa, Abscess of the Apocrine Sweat Glands: A Study of the Clinical and Pathologic Features, with a Report of Twenty-Two Cases and a Review of the Literature." Discussed by Drs. William H. Goeckerman, Los Angeles; Donald M. Pillsbury, Philadelphia, and Henry A. Brunsting, Toledo, Ohio.

Dr. Duncan O. Poth, San Antonio, Texas, read a paper on "Tumor-like Keratoses." Discussed by Drs. H. J. Templeton, Oakland, Calif.; R. H. Crockett, San Antonio, Texas; C. F. Lehmann, San Antonio, Texas; M. T.-R. Maynard, San Jose, Calif.; James H. Mitchell, Chicago; Fred D. Weidman, Philadelphia; W. F. Spiller, Galveston, Texas, and Duncan O. Poth, San Antonio, Texas.

Dr. Fred D. Weidman, Philadelphia, read a paper on "Acute Urticaria Polycythemia with Positive Oxidase Reaction in Sections and in Lesions in Situ." Discussed by Drs. J. Gardner Hopkins, New York; Joseph V. Klauder, Philadelphia; R. H. Crockett, San Antonio, Texas; Jesse Ettelson, Portland, Ore., and Fred D. Weidman, Philadelphia.

Dr. John F. Madden, St. Paul, read a paper on "Cholesterol Studies and Low Fat Diet in Psoriasis." Discussed by Drs. Richard J. Bailey, Spokane, Wash.; George V. Kulchar, San Francisco, and John F. Madden, St. Paul.

Drs. Carl W. Laymon and Harry A. Cumming, Minneapolis, presented a paper on "Sensitiveness of the Skin to X-Rays Following the Ingestion of Arsenic." Discussed by Drs. W. H. Guy, Pittsburgh; Donald M. Pillsbury, Philadelphia, and Carl W. Laymon, Minneapolis.

Dr. J. W. Tedder, New Orleans, read a paper on "Sulfanilamide Dermatitis." Discussed by Drs. Marcus B. Caro, Chicago; Stephan Epstein, Marshfield, Wis.; Ben A. Newman, Los Angeles, and J. W. Tedder, New Orleans.

On motion of Dr. Harold N. Cole, Cleveland, a vote of appreciation was passed for the very successful meeting and the hospitality of the San Francisco members.

An expression of appreciation was extended to the retiring officers for their efforts and for the interesting program.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Robert T. Legge, Berkeley, Calif.

Dr. Robert T. Legge, Berkeley, Calif., read the chairman's address, entitled "Industrial Medicine of Tomorrow."

Drs. R. R. Sayers and J. J. Bloomfield, Washington, D. C., presented a paper on "Public Health Aspects of Industrial Hygiene." Discussed by Drs. L. D. Bristol, New York; H. W. Gibbons, Sacramento, Calif., and R. R. Sayers, Washington, D. C.

Dr. R. T. Johnstone, Los Angeles, read a paper on "Industrial Medicine's Challenge to the Internist." Discussed by Drs. Leopold Brahdy, New York; Dwight O'Hara, Boston; August F. Knoefel, Terre Haute, Ind., and A. T. McCormack, Louisville, Ky.

Dr. A. G. Kammer, Indiana Harbor, East Chicago, Ind., read a paper on "Medical Supervision of Benzene Plant Workers." Discussed by Drs. Peter K. Knoefel, Louisville, Ky.; R. R. Sayers, Washington, D. C.; J. M. McCullough, Crockett, Calif., and A. G. Kammer, Indiana Harbor, East Chicago, Ind.

Dr. Carey P. McCord, Detroit, read a paper on "Noise and Its Effects on Human Beings." Discussed by Drs. Vern O. Knudsen, Los Angeles; Leopold Brahdy, New York, and Carey P. McCord, Detroit.

THURSDAY, JUNE 16—AFTERNOON

Dr. R. H. Riley, Baltimore, read a paper on "Maryland's Program for the Control of Tuberculosis." Discussed by Drs.

Frank L. Kelly, Berkeley, Calif.; Jesse D. Cook, Olive View, Calif.; Roy L. Cleere, Denver; Robert E. Plunkett, Troy, N. Y., and R. H. Riley, Baltimore.

Dr. Louis Cohen, Philadelphia, read a paper on "Hematogenous Tuberculosis and Silicosis." Discussed by Drs. Philip J. Hodes, Philadelphia; Frederick Slyfield, Seattle; Philip H. Pierson, San Francisco; Jacob Gershon-Cohen, Philadelphia, and Louis Cohen, Philadelphia.

Dr. Nina Simmonds, San Francisco, read a paper on "Recent Researches in Nutrition in Relation to Preventive Medicine." Discussed by Drs. M. J. Rosenau, Chapel Hill, N. C.; W. A. Sawyer, Rochester, N. Y.; L. D. Bristol, New York, and Nina Simmonds, San Francisco.

Dr. Charles Armstrong, Washington, D. C., read a paper on "Studies of the Mechanism of Intranasal Infections." Discussed by Drs. Edwin William Schultz, Stanford University, Calif.; Irving J. Wolman, Philadelphia, and Charles Armstrong, Washington, D. C.

Dr. Edward S. Rogers, Albany, N. Y., read a paper on "Two and One-Half Years of Pneumonia Control in New York State." Discussed by Drs. Peter Irving, New York; G. M. Ekwurzel, San Francisco, and Edward S. Rogers, Albany, N. Y.

Drs. H. S. Diehl, A. B. Baker and Donald W. Cowan, Minneapolis, presented a paper on "Cold Vaccines: An Evaluation Based on a Controlled Study." Discussed by Drs. W. A. Sawyer, Rochester, N. Y.; L. D. Bristol, New York; Robert K. Cutter, Berkeley, Calif., and H. S. Diehl, Minneapolis.

FRIDAY, JUNE 17—AFTERNOON

The following officers were elected: chairman, Dr. I. C. Riggan, Richmond, Va.; vice chairman, Dr. H. S. Diehl, Minneapolis; secretary, Dr. W. A. Sawyer, Rochester, N. Y.; executive committee: Dr. L. D. Bristol, New York; Dr. Robert T. Legge, Berkeley, Calif., and Dr. I. C. Riggan; delegate, Dr. Stanley H. Osborn, Hartford, Conn.; Dr. R. R. Sayers, Washington, D. C.

Dr. W. P. Shepard, San Francisco, introduced the following resolution, which on motion, duly seconded, was adopted:

WHEREAS, The Section on Preventive and Industrial Medicine and Public Health has had a most profitable and enjoyable session, with excellent facilities for our purposes, and every effort has been put forth to insure our comfort and the success of our meeting; be it

Resolved, That we express our gratitude to the Honorable Mayor of San Francisco, Angelo J. Rossi, and to the Director of Health of San Francisco, Dr. Jacob C. Geiger, for their hospitality and generosity.

Dr. W. P. Shepard, San Francisco, introduced the following resolution, which on motion, duly seconded, was adopted:

WHEREAS, The professional medical fields represented in this section are subject to rapid and increasing changes at this time; and

WHEREAS, The section is composed of three separate and distinct fields of specialization; and

WHEREAS, The American Medical Association has recently formed a Council on Industrial Health, with which this section will wish to work in close cooperation; be it

Resolved, That it is the sense of this section that the section delegate and alternate to the House of Delegates should hereafter serve not more than two terms, totaling four years.

Dr. Ernest C. Dickson, San Francisco, read a paper on "Coccidioidomycosis: The Preliminary Acute Infection with Fungus Coccidioides." Discussed by Drs. K. F. Meyer, San Francisco; Kenneth H. Abbott, Ontario, Calif., and Ernest C. Dickson, San Francisco.

Dr. W. M. Dickie, Berkeley, Calif., read a paper on "Health of the Migrant." Discussed by Drs. Myrnie A. Gifford, Bakersfield, Calif.; A. T. McCormack, Louisville, Ky.; Mary C. Baldwin, Riverside, Calif.; Peter Cohen, Santa Maria, Calif., and W. M. Dickie, Berkeley, Calif.

Dr. Henry A. Luce, Detroit, read a paper on "The Next Great Battle for Soldiers of Medicine." Discussed by Drs. J. N. Baker, Montgomery, Ala., and A. T. McCormack, Louisville, Ky.

Dr. James Houlose, Long Beach, Calif., read a paper on "The Contribution of Mental Hygiene to Education on the Elementary Level." Discussed by Dr. Frank E. Sawyer, Oakland, Calif.

Dr. Forrest N. Anderson, Los Angeles, read a paper on "Some Physiologic Concepts in Mental Hygiene." Discussed by Dr. L. D. Bristol, New York.

SECTION ON UROLOGY

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Albert J. Scholl, Los Angeles.

The chairman appointed Dr. H. C. Bumpus Jr., Pasadena, Calif., to act on the executive committee in the absence of Dr. W. E. Walther, New Orleans.

Dr. E. Perry McCullagh, Cleveland, read a paper on "Treatment of Testicular Deficiency with Testosterone Propionate." Discussed by Drs. H. L. Kretschmer, Chicago; George G. Reinle, Oakland, Calif.; R. V. Day, Los Angeles; L. F. Hawkins, Brainerd, Minn., and E. Perry McCullagh, Cleveland.

Drs. C. F. Schroeder, Wyandotte, Mich., and R. E. Cumming, Detroit, presented a paper on "Resection of the Superior Hypogastric Plexus and the Sacral Sympathetic Ganglions for the Relief of Bladder Pain." Discussed by Drs. Alexander B. Hepler, Seattle; J. C. Negley, Glendale, Calif.; Reed M. Nesbit, Ann Arbor, Mich., and C. F. Schroeder, Wyandotte, Mich.

The following papers were read as a "Symposium on Preliminary Investigation and Treatment of Prostatic Obstruction":

Dr. Harold C. Habein, Rochester, Minn.: "Obstruction in the Neck of the Bladder: Criteria of Operability."

Reed M. Nesbit, Ann Arbor, Mich.: "Some Refinements in the Technic of Transurethral Prostatectomy."

Edwin Davis, Omaha: "Prostatectomy or Transurethral Prostatic Resection? A Plea for the Selectionist."

These three papers were discussed by Drs. H. C. Bumpus Jr., Pasadena, Calif.; Alfred I. Folsom, Dallas, Texas; Sidney Olsen, San Francisco; B. H. Hager, Los Angeles; N. G. Alcock, Iowa City; A. B. Cecil, Los Angeles; Harold C. Habein, Rochester, Minn., and Edwin Davis, Omaha.

Drs. Robert V. Day and Harry W. Martin, Los Angeles, presented a paper on "Vesical Diverticulum: A Feature Study."

Dr. George W. Fish, New York, read a paper on "Large Solitary Scrous Cysts of the Kidney."

These two papers were discussed by Drs. Alfred I. Folsom, Dallas, Texas; T. Leon Howard, Denver; Thomas E. Gibson, San Francisco, and Robert V. Day, Los Angeles.

THURSDAY, JUNE 16—AFTERNOON

The secretary, Dr. William P. Herbst, Washington, D. C., read a report from the American Board of Urology, a communication from the Commission on Graduate Medical Education, and a communication from the Council on Industrial Health.

The meeting was called to order at 2:15 by the chairman, Dr. Albert J. Scholl, Los Angeles.

Drs. Stanley R. Woodruff, Jersey City, N. J., and Arthur H. Milbert, New York, presented a paper on "The Significance of Roentgenographic Studies of the Urinary Tract During and After Pregnancy." Discussed by Drs. Clarence G. Bandler, New York, and George C. Prather, Boston.

Dr. Albert J. Scholl, Los Angeles, read the chairman's address, entitled "Urologic Conditions Resembling Chronic Glomerulonephritis."

The following papers were read as a symposium on "Non-specific and Gonococcal Infections of the Urinary Tract":

Dr. Anson L. Clark, Oklahoma City: "Sulfanilamide Therapy in Nonspecific Infections of Urinary Tract"

Drs. Bernard Silver and H. Manning Elliott, Los Angeles: "The Treatment of Gonorrhea with Sulfanilamide."

Dr. John H. Morrissey, New York: "Surgical Procedures in the Treatment of Complications in Gonorrhea."

These three papers were discussed by Drs. A. Elmer Belt, Los Angeles; James R. Dillon, San Francisco; W. Ray Jones, Seattle; Wirt B. Dakin, Los Angeles, and Henry Helmholtz, Rochester, Minn.

Drs. John L. Emmett and John M. Kibler, Rochester, Minn., presented a paper on "Surgical Indications in Renal Tuberculosis." Discussed by Drs. John R. Hand, Portland, Ore.; Frederick Lieberthal, Chicago; J. C. Negley, Los Angeles, and William P. Herbst, Washington, D. C.

FRIDAY, JUNE 17—AFTERNOON

The following officers were elected: chairman, Dr. William P. Herbst, Washington, D. C.; vice chairman, Dr. Grayson Carroll, St. Louis; secretary, Dr. Vincent J. O'Connor, Chicago; certification board member, Dr. T. Leon Howard, Denver; delegate, Dr. H. C. Bumpus Jr., Pasadena, Calif.; alternate, Dr. George G. Reinle, Oakland, Calif.

Dr. John K. Ormond, Detroit, read a paper on "Torsion of the Testicle." Discussed by Drs. Roger W. Barnes, Los Angeles; James A. May, San Diego, Calif., and John K. Ormond, Detroit.

Dr. Duncan M. Morison, Edinburgh, Scotland, read a paper on "Routes of Absorption in Total Ureteral Obstruction: Some Further Observations." Discussed by Drs. Frank Hinman, San Francisco; Charles P. Mathe, San Francisco, and Duncan M. Morison, Edinburgh, Scotland.

The following papers were read as a symposium on "Genito-Urinary Malignant Neoplasms":

Dr. Hugh Cabot, Rochester, Minn.: "Neoplasms of the Testis: A Study of the Results of Orchidectomy With and Without Irradiation."

Dr. Henry G. Bugbee, New York: "Surgery of Genito-Urinary Malignancy."

These two papers were discussed by Drs. George C. Prather, Boston; Clark M. Johnson, San Francisco; A. Elmer Belt, Los Angeles, and Hugh Cabot, Rochester, Minn.

Dr. Norman W. Roome, Chicago, read a paper on "The Visualization of the Adrenal Glands by Air Injection." Discussed by Dr. George W. Fish, New York.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, JUNE 15—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. John Dunlop, Pasadena, Calif.

On motion regularly made and seconded, Dr. Henry W. Meyerding, Rochester, Minn., was elected delegate to the House of Delegates.

Dr. George A. L. Inge, New York, read a paper on "Synovectomy of the Knee Joint for Chronic Arthritis." Discussed by Drs. David H. Kling, Los Angeles; J. Albert Key, St. Louis, and George A. L. Inge, New York.

Dr. Henry W. Meyerding, Rochester, Minn., read a paper on "Spondylolisthesis: An Etiologic Factor in Backache." Discussed by Drs. Sylvan L. Haas, San Francisco; Charles LeRoy Lowman, Los Angeles; J. Albert Key, St. Louis, and Henry W. Meyerding, Rochester, Minn.

Drs. C. C. Coleman, Richmond, Va., and J. M. Meredith, University, Va., presented a paper on "Treatment of Fracture-Dislocation of the Spine Associated with Cord Injury." Discussed by Drs. Frederic C. Bost, San Francisco, and C. C. Coleman, Richmond, Va.

The following were appointed as a nominating committee: Dr. J. Albert Key, St. Louis, chairman; Dr. Walter G. Stern, Cleveland, and Dr. Jesse T. Nicholson, Philadelphia.

Dr. George J. Garceau, Indianapolis, read a paper on "Fractures of the Lower End of the Humerus." Discussed by Drs. J. H. Dorman, Dallas, Texas; H. W. Spiers, Los Angeles; J. Albert Key, St. Louis; Hugh T. Jones, Los Angeles; Steele F. Stewart, Los Angeles, and George J. Garceau, Indianapolis.

Dr. Charles Murray Gratz, New York, read a paper on "Fascial Adhesions in Low Back Pain and Arthritis." Discussed by Drs. Millard C. Beyer, Akron, Ohio; David R. Telson, Brooklyn; J. Albert Key, St. Louis, and Charles Murray Gratz, New York.

Dr. Steele F. Stewart, Los Angeles, read a paper on "Relation Between Birth Injuries and the Obstetric History." Discussed by Drs. Oscar L. Miller, Charlotte, N. C.; J. Albert Key, St. Louis, and Walter G. Stern, Cleveland.

THURSDAY, JUNE 16—AFTERNOON

Dr. Charles F. Nelson, Beverly Hills, Calif., read a paper on "Factors to be Considered in Bone Metabolism, with Suggestions as to the Clinical Value of Vitamin D and Parathyroid Extract."

Discussed by Drs. J. Albert Key, St. Louis; Harold E. Crowe, Los Angeles, and Charles F. Nelson, Beverly Hills, Calif.

Dr. Philip Lewin, Chicago, read a paper on "Newer Trends in Teaching Orthopedic Surgery." Discussed by Drs. J. Albert Key, St. Louis; Earl D. McBride, Oklahoma City, and Philip Lewin, Chicago.

Dr. John Dunlop, Pasadena, Calif., read the chairman's address, entitled "Transcondylar Fractures of the Humerus in Childhood."

Dr. Earl D. McBride, Oklahoma City, read a paper on "The Use of Absorbable Metal in Bone Surgery." Discussed by Drs. Charles Scott Venable, San Antonio, Texas; J. Albert Key, St. Louis, and Earl D. McBride, Oklahoma City.

Dr. C. Fred Ferciot, Lincoln, Neb., read a paper on "Dashboard Fractures of the Patella." Discussed by Drs. G. Masser Taylor, Los Angeles; August F. Knoefel, Terre Haute, Ind.; David R. Telson, Brooklyn; John Dunlop, Pasadena, Calif., and C. Fred Ferciot, Lincoln, Neb.

FRIDAY, JUNE 17—AFTERNOON

Dr. Roland Hammond, Providence, R. I., presented the report of the delegate to the House of Delegates, Dr. Henry W. Meyerding, Rochester, Minn., which was accepted.

The following officers were elected: chairman, Oscar L. Miller, Charlotte, N. C.; vice chairman, Robert V. Funsten, Charlottesville, Va.; secretary, Guy A. Caldwell, New Orleans; executive committee: Fremont A. Chandler, Chicago; John Dunlop, Pasadena, Calif., and Oscar L. Miller, Charlotte, N. C.; delegate, Willis C. Campbell, Memphis, Tenn.; alternate, Edwin W. Ryerson, Chicago. The present members of the American Board of Orthopedic Surgery, Willis C. Campbell, Memphis, Tenn., Frank R. Ober, Boston, and Fremont Chandler, Chicago, were reelected.

Dr. J. Albert Key, St. Louis, read a paper on "Common Sense in the Treatment of Acute Hematogenous Osteomyelitis." Discussed by Drs. W. D. Griesemer, Reading, Pa.; Jesse T. Nicholson, Philadelphia; John C. Wilson, Los Angeles; Earl D. McBride, Oklahoma City; Walter G. Stern, Cleveland; Charles F. Nelson, Beverly Hills, Calif., and J. Albert Key, St. Louis.

Dr. David R. Telson, Brooklyn, read a paper on "A Method of Reduction of Fractured Neck of the Femur by Transtrochanteric Skeletal Traction to Be Followed by Axial Fixation with Threaded Steel Pins, with a Report of Five Years' Follow Up on Transcervical Fixation." Discussed by Drs. Roland Hammond, Providence, R. I.; Martin B. Tinker Jr., Ithaca, N. Y., and David R. Telson, Brooklyn.

Dr. Barney J. Hein, Toledo, Ohio, read a paper on "Time Element in Fractures." Discussed by Drs. Donald C. Durman, Saginaw, Mich.; G. Masser Taylor, Los Angeles; Jesse T. Nicholson, Philadelphia; E. Payne Palmer, Phoenix, Ariz., and Barney J. Hein, Toledo, Ohio.

Dr. Walter G. Stern, Cleveland, read a paper on "Estimation of Disability After Injury." Discussed by Drs. R. W. Harbaugh, San Francisco; Earl D. McBride, Oklahoma City; Lionel D. Prince, San Francisco, and Walter G. Stern, Cleveland.

Dr. Charles S. Young, Los Angeles, read a paper on "The Operative Treatment of Pes Planus." Discussed by Drs. Maynard Harding, San Diego, Calif.; Arthur L. Fisher, San Francisco; Charles LeRoy Lowman, Los Angeles, and Charles S. Young, Los Angeles.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Henry L. Bockus, Philadelphia.

Dr. Louis F. Bishop Jr., New York, read a paper on "Gastroenterology in the Practice of Cardiology." Discussed by Dr. John R. Twiss, New York.

Dr. Andrew C. Ivy, Chicago, read a paper on "The Effect of Smoking on the Activities of the Alimentary Tract." Discussed by Drs. Sidney A. Portis, Chicago, and Andrew C. Ivy, Chicago.

Drs. Martin E. Rehfsuss and Guy M. Nelson, Philadelphia, presented a paper on "Gallbladder Infection, Its Experimental

Production and Attempts at Specific Therapy." Discussed by Drs. Garnett Cheney, San Francisco, and Guy M. Nelson, Philadelphia.

Dr. Paul C. Blaisdell, Pasadena, Calif., read a paper on "Operative Injury to the Anal Sphincter Mechanism." Discussed by Dr. Malcolm R. Hill, Los Angeles.

Drs. Claude C. Tucker and C. Alexander Hellwig, Wichita, Kan., presented a paper on "Proctologic Tumors: Diagnostic Difficulties and Pathologic Changes." Discussed by Drs. Curtice Rosser, Dallas, Texas; L. E. Brown, Corona, Calif.; Edward G. Martin, Detroit, and Claude C. Tucker, Wichita, Kan.

Dr. Wendell G. Scott, St. Louis, read a paper on "Recording the Movements of the Gastrointestinal Tract by Roentgen Kymography." Discussed by Drs. Charles W. Duden, St. Louis, and Wendell G. Scott, St. Louis.

Dr. Sara M. Jordan, Boston, read a paper on "Medical Aspect of Cancer of the Stomach." Discussed by Drs. Felix Cunha, San Francisco; George M. Underwood, Dallas, Texas, and Sara M. Jordan, Boston.

Dr. Harry Gauss, Denver, read a paper on "Gastrointestinal Symptoms in Disease of the Brain." Discussed by Drs. Edward G. Billings, Denver, and Theodore L. Althausen, San Francisco.

THURSDAY, JUNE 16—MORNING

Dr. Henry L. Bockus, Philadelphia, read the chairman's address, entitled "Training of the Gastroenterologic Internist."

The following papers were read as a symposium on "Ulcerative Colitis":

Dr. Thomas T. Mackie, New York: "The Medical Management of Chronic Ulcerative Colitis."

Drs. Elmer G. Wakefield and Charles W. Mayo, Rochester, Minn.: "Functional or Sociologic Disorders of the Colon: Medical and Surgical Considerations."

Dr. Thomas E. Jones, Cleveland: "The Surgical Treatment of Ulcerative Colitis."

Drs. John H. Willard, Philadelphia; J. F. Pessel, Trenton, N. J., and J. Warren Hundley, Philadelphia: "Prognosis of Ulcerative Colitis."

These four papers were discussed by Drs. William Fitch Cheney, San Francisco; John H. Fitzgibbon, Portland, Ore.; William C. Boeck, Los Angeles; Arthur L. Bloomfield, San Francisco; Julian M. Ruffin, Durham, N. C.; S. L. Bernstein, Cleveland; Sidney A. Portis, Chicago; Joseph Felsen, Brooklyn; A. H. Aaron, Buffalo; Thomas T. Mackie, New York; Elmer G. Wakefield, Rochester, Minn.; Thomas E. Jones, Cleveland, and J. F. Pessel, Trenton, N. J.

Drs. Leo R. Hardt, Morris Weissman and John S. Coulter, Chicago, presented a paper on "Studies on Treatment in Intestinal Tuberculosis." Discussed by Drs. Descum C. McKenney, Buffalo; Harry Gauss, Denver; Clement L. Martin, Chicago, and Morris Weissman, Chicago.

Dr. Martin S. Kleckner, Allentown, Pa., read a paper on "A Review of a Group of Proctologic Operations Using Spinocain as an Anesthetic." Discussed by Drs. Dudley A. Smith, San Francisco; Curtice Rosser, Dallas, Texas, and Martin S. Kleckner, Allentown, Pa.

Dr. Robert Elman, St. Louis, read a paper on "Intravenous Alimentation with Special Reference to Protein (Amino Acid) Metabolism." Discussed by Drs. Theodore L. Althausen, San Francisco; Thomas T. Mackie, New York, and Robert Elman, St. Louis.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Dr. Descum C. McKenney, Buffalo; vice chairman, Dr. A. H. Aaron, Buffalo; secretary, Dr. J. A. Bargen, Rochester, Minn.; executive committee: Dr. Louis A. Buie, Rochester, Minn.; Dr. Henry L. Bockus, Philadelphia, and Dr. Descum C. McKenney, Buffalo; delegate, Dr. Curtice Rosser, Dallas; alternate, Dr. Louis A. Buie, Rochester, Minn.; chairman Committee on Section Exhibit, Dr. Sara M. Jordan, Boston.

At the request of the chairman, the secretary read the following resolution:

Resolved, That the Section on Gastro-Enterology and Proctology of the American Medical Association recommend to the American Medical Association meeting here today that it records its emphatic opposition to any measure such as the proposed "State Humane Pound Law" which will

hinder or curtail animal experimentation as conducted by those fully qualified in biology and medicine. It is the belief of this society that the present level of health and humane protection of man and animals and further advance in our knowledge of the phenomena of life can be maintained only by constant vigilance and by continued study of the nature of vital processes through the experimental investigation of living animals. Every effort should be made to provide the necessary animals for scientific studies rather than to interfere by the passage of hampering legislation.

On motion made by Dr. Curtice Rosser, Dallas, Texas, seconded by Dr. Sara M. Jordan, Boston, the resolution was adopted.

Dr. J. McDonald Milligan, Elgin, Ill., read a paper on "Clinical Observations on a Group of Ulcer Cases." Discussed by Drs. Grant H. Lanphere, Los Angeles; Fred H. Kruse, San Francisco; Sara M. Jordan, Boston; John H. Fitzgibbon, Portland, Ore., and J. McDonald Milligan, Elgin, Ill.

Drs. Frederic E. Templeton and A. W. Marcovich, Chicago, presented a paper on "The Value of Roentgenologic Demonstration of the Crater in the Duodenal Ulcer." Discussed by Drs. Theodore L. Althausen, San Francisco, and Frederic E. Templeton, Chicago.

Dr. David J. Sandweiss, Detroit, read a paper on "Sex Hormones in Peptic Ulcer." Discussed by Drs. Andrew C. Ivy, Chicago, and David J. Sandweiss, Detroit.

Drs. Joseph Bank, Phoenix, Ariz., and Roby John F. Renshaw, Los Angeles, presented a paper on "Gastritis: Correlation of Gastric Analysis and Clinical Observations with Gastroscoy." Discussed by Dr. Elmer B. Freeman, Baltimore, read a paper on "Gastroscoy as Compared with Other Methods of Diagnosis in Gastric Lesions."

These two papers were discussed by Drs. Roby John F. Renshaw, Los Angeles; Milford Owen Rouse, Dallas, Texas; P. E. T. Hancock, London, England; John H. Fitzgibbon, Portland, Ore.; Frederic E. Templeton, Chicago; Joseph Bank, Phoenix, Ariz., and Elmer B. Freeman, Baltimore.

Dr. James F. Weir, Rochester, Minn., read a paper on "Some Forms of Hepatitis Not Commonly Recognized." Discussed by Drs. Dwight L. Wilbur, San Francisco; Sidney A. Portis, Chicago; Edgar Wayburn, San Francisco, and James F. Weir, Rochester, Minn.

Dr. Virgil E. Simpson, Louisville, Ky., read a paper on "Strongyloidosis: A Discussion of Strongyloid Infestation with Emphasis on Its Therapy." Discussed by Dr. Thomas T. Mackie, New York.

Dr. Harry E. Bacon, Philadelphia, read a paper on "Extra-rectal Metastatic Growths from Upper Abdominal Malignant Neoplasms." Discussed by Drs. Newton D. Smith, Rochester, Minn.; William H. Daniel, Los Angeles; Henry L. Bockus, Philadelphia; A. H. Aaron, Buffalo, and Harry E. Bacon, Philadelphia.

SECTION ON RADIOLOGY

WEDNESDAY, JUNE 15—MORNING

The meeting was called to order by the chairman, Dr. B. R. Kirklin, Rochester, Minn.

The chairman appointed Dr. John W. Pierson, Baltimore, to serve on the executive committee in the absence of Dr. Ross Golden, New York.

Dr. Harry Shay, Philadelphia, read a paper on "The Thymus: Studies of Some Changes in the Gonads and Pituitary Following Destruction of the Thymus by Roentgen Irradiation." Discussed by Drs. Edward L. Jenkinson, Chicago; Henry J. Ullmann, Santa Barbara, Calif., and Clyde K. Hasley, Detroit.

Drs. Harry H. Bowing and Robert E. Fricke, Rochester, Minn., presented a paper on "Factors Influencing the Radio-sensitivity of Malignant Neoplasms of the Uterine Cervix." Discussed by Drs. William P. Healy, New York; Henry L. Schmitz, Chicago, and Henry J. Ullmann, Santa Barbara, Calif.

Dr. H. D. Kerr, Iowa City, read a paper on "The Irradiation of Kidney Tumors in Children." Discussed by Dr. Miley B. Wesson, San Francisco.

Dr. Justin J. Stein, Hines, Ill., read a paper on "Apical Lung Tumors." Discussed by Dr. L. H. Garland, San Francisco.

Drs. Richard Dresser and Roger C. Graves, Boston, presented a paper on "Supervoltage Roentgen Treatment of Carcinoma of the Bladder." Discussed by Drs. Robert S. Stone, San

San Francisco; L. H. Garland, San Francisco; Henry J. Ullmann, Santa Barbara, Calif., and John T. Murphy, Toledo, Ohio.

Drs. James F. Kelly and D. Arnold Dowell, Omaha, presented a paper on "The Roentgen Treatment of Acute Peritonitis and Other Infections with Mobile Apparatus." Discussed by Drs. Frank E. Butler, Portland, Ore.; Frederick William O'Brien, Boston; R. H. Crockett, San Antonio, Texas; Wright Clarkson, Petersburg, Va.; Howard B. Hunt, Omaha; John J. Masterson, Brooklyn, and Henry J. Ullmann, Santa Barbara, Calif.

THURSDAY, JUNE 16—MORNING

A joint meeting was held with the Section on Pediatrics. The proceedings are reported in the minutes of that section.

FRIDAY, JUNE 17—MORNING

The following officers were elected: chairman, Dr. Raymond Taylor, Los Angeles; vice chairman, Merrill Sosman, Boston; secretary, Dr. John T. Murphy, Toledo, Ohio; delegate, Dr. Edward H. Skinner, Kansas City, Mo.; alternate, Dr. Eugene P. Pendergrass, Philadelphia; representative of the Board of Radiology, John W. Pierson, Baltimore.

Dr. B. R. Kirklin, Rochester, Minn., read the chairman's address, entitled "Lipoid Pneumonitis."

Dr. William E. Howes, Brooklyn, read a paper on "Planimetry: Its Application to Thoracic Diagnosis."

Dr. Sherwood Moore, St. Louis, read a paper on "Body Section Radiography in Surgical Conditions."

These two papers were discussed by Dr. Robert R. Newell, San Francisco, and Dr. L. H. Garland, San Francisco.

Dr. Jacob Abowitz, Los Angeles, read a paper on "Hydro-nephrosis Caused by Aberrant Renal Blood Vessels Demonstrated by Intravenous Urography." Discussed by Dr. A. A. Kutzmann, Los Angeles.

Dr. J. C. Bell, Louisville, Ky., read a paper on "Further Observations of the X-Ray Manifestations of Amebic Infections of the Large Bowel." Discussed by Dr. B. R. Kirklin, Rochester, Minn.

Dr. Joseph F. Elward, Washington, D. C., read a paper on "Epiphysitis of the Capitellum of the Humerus." Discussed by Drs. Carl H. Parker, Pasadena, Calif., and John W. Pierson, Baltimore.

Drs. Wilbur P. Bailey and William V. Knoll, Los Angeles, presented a paper on "Gastrocolic Fistulas." Discussed by Dr. J. D. Coate, Oakland, Calif.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the San Francisco session was characterized by the high caliber of exhibits presented and the continuous and sustained interest shown by the ever present crowds in the aisles. There were 167 exhibits in all, of which 140 were presented by individual exhibitors, sixteen by government and national organizations, nine exhibits of organized medicine presented by the California Medical Association, Illinois State Medical Society, Indiana State Medical Association, and the headquarters group of the American Medical Association, and two special exhibits subsidized by the Board of Trustees.

The special exhibit on anesthesia was presented under the auspices of a committee composed of Ralph M. Waters, chairman, Madison, Wis.; P. J. Hanzlik, San Francisco; Chauncey D. Leake, San Francisco, and Philip D. Woodbridge, Boston. Demonstrations were given continuously throughout the week by a competent corps of anesthetists. A pamphlet describing the exhibit was distributed.

The special exhibit on fractures was presented under the auspices of a committee composed of Kellogg Speed, chairman, Chicago; Frank D. Dickson, Kansas City, Mo., and Walter Estell Lee, Philadelphia. More than fifty physicians from various parts of the country assisted with the demonstrations, and a pamphlet describing the exhibit was distributed. Acknowledgment is made to Major General C. R.

Reynolds, the Surgeon General, United States Army, Washington, D. C.; Colonel Roger Brooke, M. C., United States Army, Letterman General Hospital, San Francisco; Lieutenant Colonel Norman T. Kirk, M. C., United States Army, Letterman General Hospital, San Francisco; Dr. C. H. Chandler, dean, Stanford University Medical School, San Francisco, and Mrs. Mitchell and Mrs. McMurray, nurses from the Stanford University Hospital, San Francisco, for the efficient service which they rendered in connection with the fracture exhibit. Appreciation is also expressed to Dr. Carleton Mathewson Jr., local representative in San Francisco for the Fracture Exhibit, for his excellent cooperation.

Other features of the San Francisco session included a Symposium on Industrial Dermatoses by the Section on Dermatology and Syphilology presented in cooperation with the United States Public Health Service, and motion picture programs by the Section on Surgery, General and Abdominal, Section on Obstetrics and Gynecology, Section on Ophthalmology, and Section on Orthopedic Surgery, shown in spaces adjoining the exhibits of those sections.

An endeavor was made to correlate the exhibits with papers read before the various sections of the Scientific Assembly, with the result that forty-nine papers were accompanied by material in the Scientific Exhibit.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

CLASS I

(Awards in Class I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation.)

The GOLD MEDAL to A. C. Ivy, R. R. Greene and M. W. Burrill of Northwestern University Medical School, Chicago, for exhibit illustrating experimentally produced intersexuality in the rat.

The SILVER MEDAL to Hermann Sommer, Hooper Foundation, University of California Medical Center, San Francisco, for exhibit illustrating plankton and paralytic shellfish poisoning.

The BRONZE MEDAL to H. J. Corper, National Jewish Hospital, Research Department, Denver, for exhibit illustrating immunity in tuberculosis; historical and experimental.

CERTIFICATES OF MERIT, Class I, are awarded to the following (alphabetically arranged):

Sherwood Moore, St. Louis, for exhibit illustrating body section radiography.

Edwin E. Osgood, University of Oregon, Portland, for exhibit illustrating culture of human marrow as an aid in the evaluation of therapeutic agents.

David J. Sandweiss, H. C. Saltzstein and A. A. Farhman, Detroit, for exhibit illustrating the relation of sex hormones to peptic ulcer.

In addition, the following exhibits are deemed worthy of honorable mention (alphabetically arranged):

That of William Osler Abbott, University of Pennsylvania, Philadelphia, and Charles G. Johnston, R. J. Noer, Grover C. Penberthy, J. C. Kenning and J. E. Lofstrom, Wayne University College of Medicine, Detroit, on acute intestinal obstruction.

That of John A. Marshall, University of California Medical Center, San Francisco, on clinical dental pathology.

CLASS II

(Awards in Class II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation.)

The GOLD MEDAL to Frank W. Konzelmann, Edward Weiss, Lawrence W. Smith, Walter I. Lillie and Edwin S. Cant,

Philadelphia, for exhibit illustrating cardiovascular-renal disease, clinical and pathologic correlation.

The SILVER MEDAL to Philip Lewin, Chicago, for exhibit illustrating newer concepts and methods of teaching orthopedic surgery.

The BRONZE MEDAL to R. J. Reitzel, S. P. Lucia, Department of Medicine, and Karl F. Meyer, Hooper Foundation for Medical Research, University of California Medical School, San Francisco, for exhibit illustrating clinical and epidemiologic demonstration of various infectious diseases.

CERTIFICATES OF MERIT, Class II, are awarded to the following (alphabetically arranged):

John O. Bower, John C. Burns and H. A. K. Mingle, Philadelphia, for exhibit illustrating comparative study of the reparative processes in the gastrointestinal mucosae following division and suture with special reference to very fine catgut sutures.

Robert A. MacArthur, Detroit, for exhibit on hematuria.

Henry W. Meyerding, Mayo Clinic, Rochester, Minn., for exhibit illustrating spondylolisthesis, an etiologic factor in backache.

Gordon B. New, F. A. Figi, F. Z. Havens and J. B. Erich, Mayo Clinic, Rochester, Minn., for exhibit illustrating deformities of the face, correction by plastic surgery.

Rudolph Skarda, University of California Medical Center, San Francisco, for exhibit illustrating anatomicosurgical preparations.

In addition, the following exhibits are deemed worthy of HONORABLE MENTION (alphabetically arranged):

That of LeRoy C. Abbott, F. C. Bost and John B. Saunders, San Francisco, on leg lengthening and fractures of the hip.

That of Albert D. Davis, San Francisco, on plastic surgery.

That of L. H. Garland and A. V. Pettit, San Francisco, on prediction of certain types of difficult labor by pelviography; an obstetric and radiologic investigation.

That of A. C. Scott, Scott and White Hospital, Temple, Texas, on mammary tumors; diagnosis and treatment.

Special citation is made of the following exhibits:

That of the Indiana State Medical Association, Bureau of Publicity and the Executive Committee, Indianapolis, on an antidote for state medicine—the preventive medical health program of the Indiana State Medical Association.

That of Elliott P. Joslin, Louis I. Dublin, Howard F. Root and Herbert H. Marks, Boston and New York, on advances in the treatment of diabetes mellitus. (Dr. Joslin has previously received a medal in the Scientific Exhibit for his work on diabetes.)

That of the Symposium on Industrial Dermatoses presented under the auspices of the Section on Dermatology and Syphilology of the American Medical Association and the United States Public Health Service.

That of the United States Navy, Medical Department, on medical equipment and practice in naval training schools, hospitals, aviation, submarines and marine corps. (The United States Navy has previously received a Special Certificate of Merit in the Scientific Exhibit on this subject.)

EDUCATIONAL CLASSIFICATION

A SPECIAL CERTIFICATE OF MERIT is awarded to the Advisory Board of Medical Specialties, Pittsburgh, for its exhibit of charts, graphs and literature describing the work of the board.

SPECIAL EXHIBITS (SUBSIDIZED)

The Committee on Awards commends particularly the special exhibits on anesthesia and fractures sponsored by the American Medical Association.

RECOMMENDATIONS

The Committee on Awards believes that the method of correlating the Scientific Exhibit with the Scientific Assembly by the appointment of section exhibit representatives is of advantage and should be continued.

The Committee appreciates the difficulties encountered in securing proper accommodations for the Scientific Exhibit; it recommends, however, that special consideration be given to this problem in future years so that sufficient space may be available to accommodate the increasing number of physicians who visit the exhibit and so that a suitable environment may be secured which will be in keeping with the high standard of the exhibits.

The Committee believes that the American Medical Association owes a debt of gratitude to the Committee on Scientific Exhibit of the Board of Trustees, to the Advisory Committee, and to Dr. Thomas G. Hull, director of the Scientific Exhibit.

The Committee cannot commend too highly the arrangements, general and special, the efficient management, the instructiveness and the scientific as well as practical value of the exhibit. The exhibitors, in many cases at personal sacrifice, present exhibits prepared by modern methods and devices for the illustration of recent advances in the various fields of medicine.

EBEN J. CAREY, Chairman, Milwaukee.
H. C. BUMPUS JR., Pasadena.
DEAN LEWIS, Baltimore.

EDITORIAL COMMENT ON THE ANNUAL SESSION

Each year the annual session of the American Medical Association stimulates numerous editorial comments in the newspapers. Following is a selection of a few from leading city publications:

HONEST MEN SPEAK WITH FRANKNESS AND SINCERITY

San Francisco Chronicle

The proceedings of the American Medical Association convention in San Francisco disclosed that the profession is in better health than might have been supposed from what some outside diagnosticians have said about it.

There has been and doubtless will continue to be lay criticism of some factors in the practice of medicine, extravagant claims and restrictions under extreme ethical codes. But what the lay critics have had to say upon such subjects seems almost flattering by comparison with what the medical speakers said before the convention gatherings.

These men were doctors, speaking to doctors. They lashed their fellow practitioners and themselves no less for offenses

which, reduced to essentials, mean little more than that the doctors are not superhuman.

Frankly and with admirable sincerity they discussed problems of their profession, deficiencies in the sum of medical knowledge, the pursuits of vain hopes that experience has proved to be vain. And as they spoke their fellow physicians listened with respect and attention.

It was a demonstration of honesty and high purpose that would be difficult to any except a gathering of medical men. Such self accusations from a political convention or a gathering of almost any other vocational or avocational group would be unthinkable. Yet the reporters covering these meetings heard men of high professional standing discuss openly, and without imposing any seal of confidence, subjects which would put any other group on the defensive.

When men dedicated to so lofty a duty come down off the pedestal to speak as frankly and sincerely as did the doctors at the convention, they justify the confidence that millions place in them. They disclose that their professional activity is vigorous and determined to go forward into the battle for humanity, in which they confess their present advance has been a series of skirmishes with mysterious and malignant enemies.

CONSERVATIVE MEDICINE

The Philadelphia Evening Ledger.

It has been claimed that only the conservatism of organized medical men is opposed to national health insurance and socialized medical services. But criticism of the American Medical Association is likely to be loudest from those who, for various reasons, are not its members. Ambitious young doctors with insufficient practices may resent the caution and conservatism of their elders. Others believe, or hope, that a system of socialized medicine would give them better and more profitable opportunities than private practice.

The A. M. A. has not weakened much in its opposition to federal control of the medical care of the American people. Its house of delegates at the association's meetings in San Francisco rejected a number of resolutions which, in effect, challenged the policy of the association in respect to socialized medicine.

That policy was reaffirmed. Its essentials are that the association is opposed to governmental or lay bodies taking over the administration of medical care under any plan, and that the medical profession does not admit that the needs of the nation for low-cost or tax-paid medical services are accurately known.

It would be dangerous, without doubt, for the nation's health and medical care to be placed in political hands. Arguments for socialized medicine, for the most part, are based on an assumption that the medical profession in America is in some degree a racket, its members more concerned for their fees than for the public welfare. None of this has been proved. The A. M. A. wisely insists that until the true facts are known the medical profession deserves, at least, the benefit of the doubt, and that it would be sheer folly to embark on a program of socialized medicine without a much more thorough study of the problem than has so far been made.

"NEW DEAL" IN MEDICINE

Indianapolis Star

The New Deal reformers apparently are insistent on undermining the work of the medical profession in their crusade to impose a mass of socialistic theories on the country. A strange note has been injected into the convention of the American Medical Association at San Francisco by those who seek to dominate the avenues through which federal paternalism can destroy the tradition of individual initiative and responsibility.

Dr. Warren F. Draper, as administration spokesman, either has been deluded by governmental propaganda or else compelled to deliver its socialistic message. He is an assistant surgeon general, representing the government's interdepartmental committee to coordinate health and welfare activities. He also is a member of the medical organization's house of delegates, the governing body of the A. M. A.

The legislative group promptly declined to accept many of Dr. Draper's statements, which obviously were either exaggerated or entirely out of order in a session concerned with medical progress rather than the New Deal's social theories.

The administration spokesman declared that the government would act if the medical profession failed to display "progressive leadership." He added that "one third of our people are not going to remain ill fed, ill housed, ill cared for in sickness." Dr. Draper might have added that most of this one third would be eliminated automatically if American business were freed of New Deal heresies and permitted to create the jobs that destroy conditions of which he complained.

The need for lower costs of medical care is urgent, yet the medical profession cannot be accused of standpatism. It has been maintaining free clinics and offering expert service in charity cases for years. The poor housing and insufficient food of which Dr. Draper lamented so tearfully are not the responsibility of the medical profession. Both would be eliminated in large part if the New Deal were scrapped and recovery permitted to function in the place of socialistic reform.

The public should not be deceived by the alluring propaganda of state medicine, which inevitably means lower professional standards and service. It is true that the nation's organized doctors bear a major responsibility in cooperating with hospitals and institutions to reduce the cost of medical care. To be effective, these reforms must be devised by practical experts and not imposed by governmental theorists.

POVERTY AND SICKNESS

New York Times

To Miss Josephine Roche's "overwhelming central fact" that "with poverty goes not only a higher rate of sickness but a deficiency of medical care," the American Medical Association replies: "This raises the question whether the economic factor is not of greater importance than is lack of medical care in the causation of illness."

No one has ever claimed that the economic factor is not of major importance in dealing with the problem of the medically indigent. Nor has any one claimed that it was the function of organized medicine to formulate plans for better housing or improving working conditions in mines and factories and thus to raise the level of the general health. On the other hand, there is a legitimate claim on the association for plans which will bring the best medical care at the lowest possible cost, even free where necessary, to the quarter of a million women who must do without a physician's aid in childbirth, the thousands of young men and women who succumb needlessly to tuberculosis, the forty-four states that have no pneumonia control program, the infants in outlying districts who still die at a rate which is abnormally high. Thus far the association has opposed group medical service, the cooperative purchase of medical advice, health insurance of any type, some public clinics established by state health authorities, government grants to stimulate research and improve medical education; in a word, any encroachment on the traditional social and economic prerogatives of the private practitioner. It can fairly be said that in this respect it has failed to adapt itself to a changing social order—failed to realize that the problem of medical care is not the concern of physicians alone.

Some of the officers and leaders of the American Medical Association are to participate in the Interdepartmental Committee Conference which Miss Roche has arranged in Washington. What will be their attitude? Despite the adoption of an unpromising resolution which trusts that these official representatives "will be guided by the principles and opinions which have been repeatedly expressed by the House of Delegates," there is reason to hope that the association will assume an enlightened leadership in a movement new to this country. To fail to do this will be to invite the type of government control that it condemns and fears.

COMPULSORY IDEALISM

Baltimore Sun

Miss Josephine Roche, representing the federal government, has notified the American Medical Association that "there will be concerted public action eventually for a national health program" and that "one third of our people are not going indefinitely to remain ill fed, ill housed and ill cared for in sickness." The only question remaining, she insists, "is whether highly specialized groups, experienced and trained in ways and means of meeting human needs, are going courageously and quickly to offer all they can give in constructive and progressive leadership and help in the meeting of the vast human problems of today."

But the problem to which Miss Roche refers is but a fractional part of a larger issue. What the public as a whole and each citizen as an individual must decide is whether or not idealism can be compelled. In theory, it can. Yet it is the verdict of history that the human race never has been coerced successfully very long. Even the authority of democracy proves futile when it attempts too much. The greatest power the world ever has seen—namely, that of organized religion—was defeated when, logically enough, it endeavored to dictate to conscience.

Specifically, the medical profession is the present object of attack by those who believe that altruism can be forced. Tomorrow the lawyers or the teachers, perchance, may be commanded to socialize themselves. Sooner or later the humblest corner grocer might be driven into line. If it be fair to expropriate the physician, it certainly would be just to enslave to the state all of his contemporaries who may be possessed of "ways and means of meeting human needs." Where would the policy of subjection stop? The answer of the Communist is: Nowhere!

But does dragging down the so-called "upper" two thirds really benefit the "suppressed" and "underprivileged" one third of the population? Radicals confidently reply in the affirmative. Their more conservative neighbors are not so sure. Poverty, they argue, is not eliminated by being shared. It also might be contended that generosity ceases to be a virtue when it is prevented from being voluntary.

Only the blindest of optimists can persuade himself that "a national health program" or any authentic merit could be put into effect without the willing assistance of medical practitioners as a class. The current campaign to conscript their assistance appears to be unwise in both motivation and result. Perhaps some of its sponsors might care to remember that the average doctor already is giving his services to patients unable to pay. Under the most benign group health plan ever formulated there still would be people who could not afford expensive medical attention. The same might be said for many other luxuries, not excluding that of rest and recreation conducive to physical and mental well-being.

WHERE THE DOCTORS DO STAND

The Milwaukee Journal.

The American Medical Association is being hammered over the head editorially in some newspapers because it did not go pell-mell for state or socialized medicine in its San Francisco convention. The inference is that of a standpat organization made up of members insensible to the public need, and intent only on fee collecting.

This kind of comment makes it all the more necessary to understand where the association drew its lines, what it did and what it refused to do.

The association did not oppose a wider use of medical care. It recognized the need for a wider use and urged its realization.

The association did not dodge the problem of caring for the indigent and the borderline cases. It urged on state and county medical societies that they develop "the most accurate and complete information that will enable them . . . to maintain continuously medical care that is sufficient in amount and satisfactory in quality."

The association did not oppose group hospital insurance. It backs group hospital insurance, with proper safeguards to patient and doctor.

The association did refuse to throw the doors wide open to state medicine by indorsing some vague plan that would make the care of indigent and borderline cases, and the whole development of medicine, a burden on public treasuries, to be met by the dictatorship of bureaucracy over medical practice. If that be reaction, this country ought to be thankful for it.

What would happen if the medical men went the whole way with those advocates of state medicine who go out from Washington to make speeches at every medical convention, those doctors who are in revolt because the association will not accept European models, and those foundations with money to spend that are trying their best to fasten socialized practice on this country?

Exactly the same incompetency in regard to medical care that Harry Hopkins seems to have fastened on this country in regard to food, clothing and work—a permanent class, ever growing larger, to be provided for by the government. Do we want that? Do we want another such mistake in methods?

The association wants to keep the job within the medical profession and it thinks the state and local societies are the ones to do it. And it can be done that way. It is being done in Milwaukee County. Free care under medical decision for the truly indigent and budgeting for the borderline cases—that is, borderline cases pay what they are able to pay and no more—this plan is working out in our own area. Recent surveys have not disclosed one case of need that was not met.

Isn't that the better way? We let the doctor say whether a man is ill and needs help. The other plan would let a layman bureaucrat make the decision. Then you would have incompetency and politics mixed in, and outright graft, as they have in every European system.

This, it would seem, is the dividing line between the medical organizations and the advocates of socialized medicine.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Dr. Kress Honored.—Dr. George H. Kress, Los Angeles, newly elected secretary of the California Medical Association, was honored May 23 at a dinner of the Research Study Club and the Los Angeles Academy of Ophthalmology and Otolaryngology. The speakers included Drs. Alexander Ray Irvine, toastmaster; Harlan Shoemaker, William D. Donohue, John Mackenzie Brown, George Dock and Isaac H. Jones. Dr. Kress was presented with a traveling bag. The new activities of Dr. Kress with the state association necessitated his retirement from active practice, the state board of health, the deanship of the Los Angeles Medical Department of the University of California and the presidency of the Los Angeles County Medical Association.

Death from Rabies.—*California and Western Medicine* reports the death from rabies April 3 of a dairyman of Kings County. In March, this man noticed that one of his cows was having difficulty in swallowing. To aid the cow he placed his hand in the animal's mouth, receiving abrasions on his knuckles. The cow died that night and the laboratory gave a positive diagnosis of rabies the following day. In the afternoon treatment for rabies was instituted for the dairyman. At least twelve doses of vaccine were administered. On April 1 he had diminished reflexes, slightly stiff neck, a high temperature and was lethargic. He died April 3. At no time did he have convulsions and there was no difficulty in swallowing. Examination of the brain at Stanford University School of Medicine, San Francisco, disclosed the presence of Negri bodies, confirming the diagnosis of rabies.

FLORIDA

Society News.—The Dade County Medical Society was addressed June 7 by Drs. James L. Anderson and Ralph W. Jack, both of Miami, on "Hypoglycemic Shock Therapy" and "Diagnosis of Pregnancy" respectively. A symposium on peptic ulcer was presented before the Duval County Medical Society June 4 by Drs. Frederick K. Herpel, West Palm Beach; Herbert L. Bryans, Pensacola, and John S. Turberville, Century. The Pinellas County Medical Society devoted its meeting June 3 to a symposium on tuberculosis; the speakers were Drs. Arthur J. Logie, Jacksonville; Rollin D. Thompson, Orlando; Arnold S. Anderson, St. Petersburg, and William H. Pickett, Clearwater.

GEORGIA

New Cancer Clinic.—A new cancer treatment center has been organized at the new City-County Hospital, La Grange, completed last September, according to *Georgia's Health*. Dr. Enoch Callaway is the director of the clinic and Dr. Emory R. Park, associate director. Clinics will be held each Wednesday. With the opening of this clinic there are now eight regularly organized cancer treatment centers available in the state.

IDAHO

Plague Infection.—According to *Public Health Reports*, plague infection has been proved in tissue from one ground squirrel shot May 25, sixteen miles north of Lava Hot Springs, Bannock County.

Society News.—At a recent meeting of the Southwest Idaho Medical Society in Boise the speakers were Drs. Clifford D. Sweet, Oakland, on the child as a patient; Frederick Bost, San Francisco, spinal disorders, and Norman N. Epstein, San Francisco, diagnosis and treatment of syphilis. Dr. George W. Pierce, San Francisco, held two clinics on reconstructive surgery.

ILLINOIS

Society News.—Dr. Frederick R. Schmidt, Chicago, discussed common diseases of the skin before the Madison County Medical Society in Alton June 3. The Macoupin County Medical Society was addressed in Carlinville May 24 by Drs. Robert J. Crossen and Franz J. Arzt, St. Louis, on gynecology and newer management of threatened abortion, respectively.

Chicago

Course in Electrocardiography.—A graduate course in electrocardiography will be presented at Michael Reese Hospital by Dr. Louis N. Katz, director of cardiovascular research, August 22-September 3. It is planned to individualize the course so that at the end of the period each student will be capable of taking and properly interpreting routine electrocardiograms. Additional information may be obtained from the medical librarian at the hospital, Twenty-Ninth Street and Ellis Avenue.

Endowment for Biologic Research.—The University of Chicago will receive \$1,500,000 from the Rockefeller Foundation for research in the biologic sciences, provided an additional sum of \$500,000 can be obtained from outside sources before June 30, 1941. During the next three years the foundation will provide \$180,000 at the rate of not more than \$60,000 a year for biologic research. This grant has been made so that the equivalent of the income of the capital sum of \$1,500,000 will be available to the university during the period allowed for raising the sum of \$500,000. Should the university secure the funds in a shorter period, the temporary annual grants will be canceled. The foundation has provided grants for the support of basic laboratory research in fundamental biologic problems since 1929 and the new endowment will support this work permanently on a larger scale.

INDIANA

University News.—Miss Ruth J. McNutt, former secretary to William Lowe Bryan, LL.D., president, Indiana University, succeeded Allan Hendricks July 1 as librarian at the Indiana University School of Medicine, Indianapolis. She will serve also as library coordinator for the four libraries at the medical and dental schools, for the social service department and at the extension center.

Society News.—Dr. William M. Doughty, Cincinnati, discussed "Cancer of Oral Tissues" before the Dearborn-Ohio County Medical Society in Lawrenceburg recently. At a meeting of the Jasper-Newton County Medical Society in Morocco recently Dr. James H. Hawk, Indianapolis, spoke on puerperal infection. The Monroe County Medical Society was addressed in Bloomington May 9 by Dr. William C. MacCarty, Rochester, Minn., on "Cancer and Cancer Control."

Typhoid Outbreak in Bus Passengers.—Contaminated drinking water from a well near Angola, used by passengers of a bus line, has been found to be responsible for at least fifty-two cases of typhoid with six deaths in Indiana and several other states, according to *Public Health Reports* June 17. Cases in persons giving a history of having stopped off at Angola for meals when traveling by bus during the early part of April have been reported from Ohio, New York and Illinois, and two cases in California have been traced to this source. *Public Health Reports* suggests that other states have probably had recent isolated cases of typhoid of undetermined origin which are also attributable to this source. The onset of the majority of cases was in April; use of the water was stopped by the health officer the latter part of April.

KANSAS

Society News.—The Wyandotte County Medical Society was addressed in Kansas City May 3 by Drs. Eldon S. Miller on "Relation of Coronary Heart Disease and Diabetes Mellitus" and Don C. Peete, "Post Influenza Myocarditis." Dr. Carl O. Rice, Minneapolis, discussed "Injection Treatment of Hernia" before the society recently. Dr. Elmer L. Sevringhaus, Madison, Wis., addressed the Shawnee County Medical Society in Topeka June 6 on "Endocrine Therapy in General Practice."

KENTUCKY

Personal.—Dr. Clarence E. Bird has resigned as professor and head of the department of surgery at the University of Louisville School of Medicine, effective August 1. He plans to practice in Providence, R. I., according to the *Harvard Medical Alumni Bulletin*.

Regional Meeting.—The sixty-ninth annual meeting of the Southwestern Kentucky Medical Association was held recently in Paducah with the following speakers: Drs. Daniel L. Sexton, St. Louis, on "Endocrinology in General Practice"; Ralph L. Cook, St. Louis, "Upper Respiratory Infections in Children"; Euclid M. Smith, Hot Springs National Park, Ark., "Management of the More Common Arthritic Disorders"; William G. Johnson, Louisville, "Endocrine Glands and

Organotherapy," and Silas H. Starr, Louisville, "Postpartum Hemorrhage." Dr. Morton W. Haws, Fulton, was elected president.

LOUISIANA

Society News.—At the third annual meeting of the Louisiana-Mississippi Ophthalmological and Otolaryngological Society in New Orleans recently the guest speakers were Drs. Albert L. Brown, Cincinnati, on "Affections of the Paranasal Sinuses Involving the Optic Nerve" and Arthur M. Alden, St. Louis, "Deep Neck Infections." Officers are Drs. Francis E. Le Jeune, New Orleans, president; Daniel C. Montgomery, Greenville, vice president, and Edley H. Jones, Vicksburg, secretary. The next annual session of the society will be held in Gulfport.

MICHIGAN

The Henry Russel Award.—Dr. Franklin D. Johnston, assistant professor of internal medicine, University of Michigan Medical School, Ann Arbor, was presented May 3 with the Henry Russel award for 1938 by the university for his accomplishments and promise in medical research and teaching. Dr. Johnston graduated from the University of Michigan as an electrical engineer in 1922 but became interested in medicine when he became the first patient in diabetic coma to be treated with insulin at the University Hospital, it was reported. He graduated at the medical school in 1929.

MINNESOTA

Personal.—Dr. Demeter Kalinoff, for thirty-six years a practicing physician in Stillwater, was named to the Stillwater Hall of Fame at the annual Hall of Fame banquet recently, in recognition of "his charity, generosity and kindness in his practice among the people of Stillwater."

Society News.—Dr. Owen H. Wangenstein, Minneapolis, delivered the presidential address before the Minnesota Pathological Society May 17 on "Physiologic and Pathologic Aspects of Therapeutic Problems in Obstruction of the Bowel." Mr. A. G. Stasel, Minneapolis, was chosen president-elect of the Minnesota Hospital Association at its annual convention in Minneapolis May 21 and Dr. Peter D. Ward, superintendent of the Miller Hospital, St. Paul, was installed as president.

MISSOURI

Symposium on Cancer.—The St. Louis Medical Society was addressed recently by Drs. Frederick J. Taussig on "Present Possibilities and Future Expectations in Cancer Therapy"; Leo Loeb, "The Causes of Cancer," and Axel N. Arneson, "Fundamental Principles Underlying Radiation Therapy." Dr. Frederick W. Broderick, Bournemouth, England, discussed "The Fundamental Factor in Etiology" before a recent joint meeting of the St. Louis medical and dental societies.

New Health Districts.—The following have been placed in charge of the recently formed district health units:

Dr. Theodore L. Waddle, Dexter, district 2, consisting of Stoddard, Scott, New Madrid and Mississippi counties.

Dr. Will H. Aufranc, Kennett, district 3, consisting of Pemiscot and Dunklin counties.

Dr. Enoch M. Bryan, Fredericktown, district 4, consisting of Butler, Wayne, Bollinger, Cape Girardeau, Perry, St. Genevieve, Madison, Iron and Washington counties.

Dr. Charles W. Meinershagen, Salem, district 5, consisting of Howell, Oregon, Ripley, Carter, Reynolds, Shannon, Texas, Dent, Pulaski, Phelps and Crawford counties.

Dr. Henry H. Asher, Ozark, district unit 6, consisting of Barton, Jasper, Newton, McDonald, Dade, Lawrence, Barry, Stone, Christian, Taney, Ozark, Douglas, Webster and Wright counties.

Dr. Robert D. Wright, Osceola, district 7, consisting of Bates, Vernon, Henry, St. Clair, Cedar, Benton, Hickory, Polk, Morgan, Camden, Dallas and Laclede counties.

Some counties are continuing as independent units; that is, financed by the local authorities, and other district units have been formed but are not yet in operation.

NEW YORK

Society News.—Dr. Ward H. Cook, bureau of laboratories, department of public health, Yonkers, was chosen president of the New York State Association of Public Health Laboratories at its annual meeting in Cooperstown May 23. Dr. Gilbert J. Dalldorf, Grasslands Hospital Laboratory, Valhalla, and Mary B. Kirkbride, Sc.D., state laboratory, Albany, were elected vice president and secretary, respectively. Dr. Louis A. Siegel, Buffalo, addressed the Medical Society of the County of Niagara June 14 on endocrine therapy.

Faculty Promotions at Syracuse.—The board of trustees of Syracuse University recently approved the following promotions in the school of medicine:

Dr. John G. Fred Hiss to be professor of clinical medicine.
Dr. Maynard E. Holmes, professor of clinical medicine.
Dr. Eugene N. Boudreau, professor of clinical medicine (neurology).
Dr. Jacob J. Levy, associate professor of medicine in physical therapy.
Neal E. Artz, Ph.D., associate professor of physiologic chemistry.
Dr. Lee A. Hadley, assistant professor of medicine in physical therapy.
Dr. Noble R. Chambers, assistant professor of medicine (neurology).
Dr. Bertram S. Levinson, assistant professor of clinical medicine.
Dr. Charles George Murdock Jr., assistant professor of clinical pediatrics.
Dr. Mary F. Brew, associate professor of psychiatry.
Dr. Eugene Davidoff, assistant professor of psychiatry.

New York City

Display of Medical Military Memorabilia.—St. Luke's Hospital presented an exhibit in June of medical materials and other relics associated with the war services of members of its board of managers, medical officers and nursing staff. The display included original pictures, portraits, documents, photographs and war relics illustrating military surgery at the front, at base hospitals, ambulance and Red Cross work and in the navy on sea and shore. The hospital was represented in active World War service by more than 70 per cent of its medical staff.

Dr. Carrel Announces Retirement.—Dr. Alexis Carrel, member of the Rockefeller Institute for Medical Research, having reached the retirement age of 65, has announced that his work at the institute will be halted, his division closed and his staff disbanded July 1, 1939, according to the *New York Times*. Dr. Carrel was born in Sainte Foy les Lyon, France, June 28, 1873. He received his degree in medicine at the University of Lyon in 1900; he served as professor at his alma mater until 1902, came to the United States in 1905, and joined the staff of the Rockefeller Institute for Medical Research in 1906. In 1912 he was awarded the Nobel Prize in Medicine for success in suturing blood vessels and transplantation of organs. This was the first time the prize in medicine had been awarded in the United States. Dr. Carrel won the Dr. Sofie Nordhoff-Jung Cancer Prize in 1931 and received the eighth Cardinal Newman Award of the Newman Foundation in 1937. He is an Associate Fellow of the American Medical Association.

NORTH CAROLINA

Officers of the State Medical Board.—Dr. Lewis W. Elias, Asheville, was elected president of the state board of medical examiners at a meeting June 13 in Raleigh, and Dr. William D. James, Hamlet, was elected secretary. An entire new board was elected at the meeting of the Medical Society of the State of North Carolina in May, to serve for six years.

Society News.—At a meeting of the medical societies of Rutherford, Polk, McDowell and Cleveland counties in Rutherfordton recently, the name Thermal Belt Medical Society was adopted.—Dr. Arthur L. Daughtridge, Rocky Mount, was elected president of the North Carolina Radiological Society at its recent meeting in Pinehurst and Dr. Major I. Fleming, Rocky Mount, was reelected secretary.

Personal.—Dr. James R. Rogers, Raleigh, was honored at a meeting of the Raleigh Academy of Medicine June 10 as its oldest member. Dr. Rogers has been in active practice more than fifty years.—Dr. J. Roy Norton, assistant director of county health work on the staff of the state health department, Raleigh, has been made assistant director of the division of preventive medicine.—Dr. John S. Anderson, New Bern, health officer of Craven County, has resigned to become health officer of Cabarrus County. He succeeds Dr. Daniel G. Caldwell, Concord, who resigned because of ill health.—Dr. Wingate M. Johnson, Winston-Salem, has been elected president of the board of trustees of Wake Forest College.

OHIO

Health Survey in Toledo.—Carl E. Buck, Dr.P.H., field director, American Public Health Association, is conducting a public health survey of Toledo at the request of the Toledo Academy of Medicine. The purpose of the study is to determine the extent to which Toledo agencies are providing adequate health protection service and to recommend means by which various activities may be coordinated and the program improved.

Fifty Years of Practice.—The Mahoning County Medical Society held a testimonial dinner in honor of Dr. Harmon E. Blott, Youngstown, May 17, in recognition of his completion of fifty years in the practice of medicine and made him an

honorary member of the society. Dr. Blott graduated at Western Reserve University School of Medicine, Cleveland, in 1888. Dr. Paul D. White, Boston, was the speaker at the scientific meeting of the society.

OKLAHOMA

Changes in the Faculty at Oklahoma.—The title of emeritus professor was conferred by the University of Oklahoma School of Medicine, Oklahoma City, on Drs. Edmund S. Ferguson, professor of ophthalmology; William M. Taylor, professor of pediatrics, and John F. Kuhn, professor of gynecology, it has been announced. Dr. Leslie M. Westfall, professor of clinical ophthalmology, has been appointed to succeed Dr. Ferguson as professor and head of the department of ophthalmology; Dr. Clark H. Hall, associate professor of pediatrics, will succeed Dr. Taylor as professor and head of the department of pediatrics, and Dr. Grider Penick, associate professor of gynecology, will become professor and head of the department of gynecology, succeeding Dr. Kuhn. The appointments are effective September 1.

OREGON

Society News.—The Lincoln County Medical Society was recently organized with Drs. Wilfred S. Thurtell, Newport, as president and Orley N. Callender, Toledo, as secretary.—Dr. Ralph A. Fenton, Portland, addressed the Central Willamette Medical Society, Corvallis, in May on "Hoarseness from the Standpoint of the General Practitioner."—The annual meeting of the Southern Oregon Medical Society was held at Oregon Caves in May with Grants Pass physicians as hosts. The guest speakers were the following Portland physicians: Drs. Otis F. Akin, on "Fractures and Dislocations of the Cervical Vertebrae"; Laurence Selling, "Herniation of the Intervertebral Disks," and Homer P. Rush, "Sex Hormones." Dr. Charles T. Sweeney, Medford, president of the Oregon State Medical Society, and Mr. Clyde Foley, executive secretary of the state society, discussed organization activities. Dr. Albert F. Walter Kresse, Medford, was elected president.

PENNSYLVANIA

Society News.—Drs. Walter F. Donaldson, Pittsburgh, and James H. Corwin, Washington, addressed the Westmoreland County Medical Society at the Mountain View Hotel near Greensburg June 21 on "Medical Service—Today and Tomorrow" and "Medical Service Survey" respectively.

Personal.—Dr. Richard Weissenberg, formerly professor extraordinarius of anatomy, University of Berlin, has been appointed a fellow at the Wistar Institute of Anatomy and Biology and will undertake research at the Effingham B. Morris Biological Farm, Bristol, according to *Science*. Dr. Weissenberg served as visiting professor of cytology at Washington University School of Medicine, St. Louis, last year.

Philadelphia

New Medical Director at Jefferson Hospital.—Dr. Robert Bruce Nye, director of the Curtis Clinic at Jefferson Medical College Hospital, has been appointed medical director of the hospital. He succeeds Dr. Henry K. Mohler, who was recently appointed dean of the medical college. Dr. Nye graduated from Jefferson in 1927 and has been director of the Curtis Clinic since it was opened in 1931.

Portrait of Dr. Anspach.—The graduating class of 1938 at Jefferson Medical College presented to the college April 21 a portrait of Dr. Brooke M. Anspach, professor of gynecology. A native of Reading, Pa., Dr. Anspach graduated at the University of Pennsylvania School of Medicine in 1897. He served at his alma mater as associate in gynecology until 1921, when he became professor at Jefferson. He is a former president of the American Gynecological Society. The senior class also presented a plaque to the college April 27 commemorating the services of the late Dr. Michael A. Burns, professor of neurology.

Pittsburgh

Society News.—The Allegheny County Medical Society was addressed June 21 by Drs. Joseph W. Hampsey on "Allergic Rhinitis: Use of Nasal Smears as an Aid in Diagnosis"; Simon H. Ratner, "Tuberculosis of the Larynx"; John P. Henry, "Treatment of Varicose Veins and Leg Ulcers," and Cleophas E. Poellot, Woodville, Pa., "Lest We Forget—The Intellect."—The Pittsburgh Surgical Society was addressed June 17 by Drs. John Shelton Horsley, Richmond, Va., on "Appendicitis—Recent Improvements in Treatment" and Donald W. G. Murray, Toronto, Canada, "Heparin in the Treatment

of Postoperative Thrombosis."—Dr. Walter T. Dannreuther, New York, discussed "Supravaginal Hysterectomy—A Review of 535 Personal Cases" before the Pittsburgh Obstetrical and Gynecological Society May 14.—At a meeting of the Pittsburgh Ophthalmological Society, May 23, Dr. Stuart N. Rowe spoke on "Changes in the Eyes Resulting from Intracranial Mass Lesions."

RHODE ISLAND

Society News.—Dr. Walter C. Rocheleau, Woonsocket, president, state medical society, addressed a recent meeting of the Pawtucket Medical Association in Pawtucket on health insurance.—A symposium on hypertension and albuminuria in pregnancy was presented before the Providence Medical Association in Providence May 2; the speakers were Drs. Foster S. Kellogg, Duncan E. Reid and Harold M. Teel.

Executive Secretary Appointed.—Mr. John E. Farrell, graduate manager of athletics at Providence College for the past twelve years, has been appointed full time executive secretary of the Providence Medical Association. Mr. Farrell was graduated from Providence College and has taken graduate courses at Harvard and Boston universities. He has been engaged in newspaper and publicity work and recently initiated a course in journalism at Providence College.

TENNESSEE

Promotions at Vanderbilt.—The board of trustees of Vanderbilt University, Nashville, recently approved the following promotions in the school of medicine:

Dr. Samuel M. Bloomstein to be professor of clinical pediatrics.
Dr. Leonard W. Edwards, associate professor of clinical surgery.
Dr. Rudolph H. Kampmeier, associate professor of medicine.
Dr. Ralph M. Larsen, assistant professor of surgery and anatomy.
Dr. Guy Sydney McClellan, assistant professor of obstetrics and gynecology.

Annual Regional Meeting.—Dr. John Jackson, Dyer, was elected president of the West Tennessee Medical and Surgical Association at its forty-seventh annual session in Jackson May 26. Among the speakers were Drs. Milton S. Lewis, Nashville, on "Factors That Influence Neonatal Mortality"; Edwin J. Lipscomb, Memphis, "Fractures of the Humerus Involving the Shoulder Joint," and Arthur F. Cooper, Memphis, "Some Phases of State Medicine."

TEXAS

Society News.—Dr. Bernard H. Bayer addressed the Harris County Medical Society, Houston, recently on "Fractures of the Skull—A Study of 200 Cases."—Drs. Harry R. Levy and James H. Herndon addressed the Dallas County Medical Society May 26 on "Appendicitis, Differential Diagnosis and Treatment" and "Diagnosis in Therapy of Brucellosis" respectively.—The annual premedical banquet sponsored by the University of Texas chapter of Alpha Epsilon Delta, honorary premedical fraternity, was recently held in Austin, with Dr. Edward H. Cary, Dallas, as toastmaster. Students and faculty members from forty colleges and universities in Texas were invited. Among the speakers were Drs. Ernst W. Bertner, Houston, president-elect of the Texas State Medical Association; William S. Carter, Galveston, dean, University of Texas School of Medicine; Walter H. Moursund, Dallas, dean of Baylor University Medical School, and Kenneth H. Aynesworth, Waco, a regent of the university.—At a meeting of the Denton County Medical Society recently in Denton, the speakers were Drs. John M. Pace, Dallas, on "Transurethral Prostatic Resection" and Frank A. Selecman, Dallas, "Peritonitis."—The Hardin-Tyler Counties Medical Society was addressed in Kountze recently by Drs. Harold L. D. Kirkham and Joseph R. Theriot Jr., both of Houston, on skin grafting and emergencies in abdominal surgery, respectively.—Among others, Dr. William S. Webb, Fort Worth, discussed "Cataract Surgery" before the Tarrant County Medical Society recently.

VIRGINIA

New Rural Health Director.—Dr. Lonsdale J. Roper, recently associate director of the venereal disease program of the state health department, Richmond, has been made director of rural health for the department, succeeding Dr. Charles Howe Eller. Dr. Roper was for several years director of the department of public welfare in Portsmouth.

Mental Hygiene Advisory Board.—The following appointments to the state advisory board on mental hygiene have been announced: Drs. Joseph S. DeJarnette, superintendent of the Western State Hospital, Staunton; Joseph Blalock, superintendent of the Southwestern State Hospital, Marion; Oscar B. Darden, Westbrook Sanatorium, Richmond. Reappointed

members are Drs. Hugh C. Henry, Petersburg; George W. Brown, Williamsburg; Harvie DeJ. Coghill, Robert Finley Gayle Jr., Howard R. Masters and James Asa Shield, all from Richmond.

Joint Psychiatric Meeting.—The North Carolina Neuropsychiatric Association met with the Virginia Neuropsychiatric Society recently at the Westbrook Sanatorium, Richmond. The speakers were Drs. Bronson Crothers, Boston, on "A Pediatrician in Search of Mental Hygiene"; Maurice Barnes Woodhall, Durham, N. C., "Encephalography in the Diagnosis of Posttraumatic Psychosis and Other Sequelae of Acute Head Injuries"; Elbert A. MacMillan, Winston-Salem, "Hystero-Epilepsy" and Roy H. Long, Morganton, "A Preliminary Report on the Use of Metrazol in the Treatment of the Psychotic."

WASHINGTON

Health Institute.—Medical and civic authorities cooperated in holding a health institute in Spokane recently to acquaint the public with developments in medicine and to present a brief study of some important diseases.

Society News.—Dr. Ross E. McPhail, Lakeview, addressed the Grays Harbor County Medical Society, Elma, May 18, on "Indications and Contraindications for Thoracotomy."—Drs. Hale A. Haven and Louis H. Edmunds, Seattle, addressed the Yakima Valley Medical Society in Yakima recently on brain tumors and injuries to the knee, respectively.—Dr. Charles P. Wilson, Portland, addressed the Walla Walla Valley Medical Society at its final meeting of the season in Walla Walla May 12 on rheumatic diseases. Dr. Carl J. Johannesson was elected president.

Graduate Course at State University.—The twenty-second annual graduate medical course will be presented at the University of Washington, Seattle, July 18-22. The lecturers will be Drs. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, Baltimore; Myrie G. Peterman, professor of pediatrics, Marquette University School of Medicine, Milwaukee; Frederick H. Falls, professor of obstetrics and gynecology, University of Illinois College of Medicine, Chicago, and Leo G. Rigler, professor of radiology, University of Minnesota Medical School, Minneapolis.

WEST VIRGINIA

Society News.—Dr. Russell B. Bailey, Wheeling, discussed "Lobectomy for Lung Abscess" before the Logan County Medical Society recently.—At a meeting of the Monongalia County Medical Society in Morgantown recently Dr. William B. Morrison, Columbus, spoke on "Recognition of Protein Efficiency in the Treatment of Carcinoma of the Stomach."—Dr. Frank N. Wilson, Ann Arbor, Mich., addressed the Ohio County Medical Society recently on cardiac pain. Dr. William James Gardner, Cleveland, addressed the society May 6 on "Surgical Lesions of the Cranial Nerves."

GENERAL

Special Society Election.—Dr. McIver Woody, New York, was chosen president-elect of the American Association of Industrial Physicians and Surgeons at its annual meeting in Chicago June 10 and Dr. Clarence D. Selby, Detroit, was installed as president. Other officers are Drs. Daniel L. Lynch, Boston; Lloyd Noland, Birmingham, Ala., vice presidents, and Volney S. Cheney, Chicago, secretary.

Examination by Board of Dermatology.—If the number of candidates warrants it, the American Board of Dermatology and Syphilology will hold an examination Friday and Saturday, November 11-12, before the meeting of the American Academy of Dermatology and Syphilology in St. Louis. Should an examination be held, the latest date for receipt of applications of class B would be September 1 and of class A October 1. Further information may be obtained from the secretary, Dr. Clarence Guy Lane, 416 Marlboro Street, Boston.

Fraudulent Salesman.—Wisconsin physicians have recently reported the activities of one John Bowles, who claimed to represent the Professional Circulation Company of New York and took orders for magazines and books which the physicians never received. It is reported that Bowles was discharged by the National Medical Book Company several months ago and that firm is trying to locate him for fraudulent actions. Bowles is 5 feet 10 inches tall, wears a mustache and has dark wavy hair, blue eyes and deep lines in his face. He speaks with a slight Southern accent and was at one time a practicing dentist.

Bibliography of Medical Aeronautics.—A bibliography of aeronautical medicine, which lists book and pamphlets dealing with the medical aspects of flying, has been compiled as a part

of a Works Progress Administration project. It includes treatises by English, French, German, Italian and other foreign authors. The effects of flying on the cardiovascular system, the eye, ear, nose and throat, and the effects of altitude, parachute jumping, wind, cold and speed on the various organs and the entire system are covered in the compilation, as are fatigue and staleness, hygiene, nervous system, pathology, physical qualification, psychologic aspects, psychophysiologic aspects, sanitary aviation, accidents, air sickness, airplane ambulances and carbon monoxide poisoning. John R. Palmer, managing project supervisor, U. S. Works Progress Administration, 5111 R. C. A. Building, New York, is handling correspondence relating to the bibliography. The Institute of Aeronautical Sciences announces it will appreciate receiving additional references, corrections and criticism.

Payment of Blood Donor.—The United States Code provides that when there is filed in the General Accounting Office a claim against the United States that may not lawfully be adjusted by the use of an appropriation theretofore made, but which claim, in the judgment of the Comptroller General of the United States, contains such elements of legal liability or equity as to be deserving of the consideration of the Congress, the Comptroller General shall submit the claim to the Congress by a special report containing the facts and his recommendation thereon. The furnishing of blood for transfusion to a patient in a Veterans' Administration Facility by a salaried civilian employee of the federal government, with full knowledge that under the law and regulations of the Veterans' Administration he was not entitled to payment therefor, does not involve, in the judgment of the General Accounting Office, such elements of legal liability or equity as would justify that office in reporting it to the Congress with a recommendation that compensation be paid for the service rendered.

One Million to Infantile Paralysis Foundation.—Mr. Basil O'Connor, New York, president of the National Foundation for Infantile Paralysis, in a letter addressed to President Roosevelt June 21 announced the appointment of a general advisory committee and four subcommittees to advise the foundation on the allotment of its funds. At that time Mr. Keith Morgan, New York, chairman of the Committee for Celebration of the President's Birthday, presented to the President a check for \$1,010,000 as the principal instalment of the funds raised in the 1938 celebrations. It is expected that about \$50,000 more will be added when the auditor's report is completed. The general committee has the following members:

Dr. Irvin Abell, Louisville, Ky., President of the American Medical Association.

Dr. Philip Lewin, associate professor of orthopedic surgery, Northwestern University Medical School, Chicago.

Dr. Thomas Parran, surgeon general, U. S. Public Health Service, Washington, D. C.

Dr. Max Minor Peet, professor of surgery, University of Michigan Medical School, Ann Arbor.

Dr. Thomas M. Rivers, director, Hospital of the Rockefeller Institute for Medical Research, New York.

Dr. Rivers is chairman of the subcommittee on scientific research, of which the members are Dr. Donald B. Armstrong, Metropolitan Life Insurance Company, New York; Dr. George W. McCoy, U. S. Public Health Service, Washington, D. C., and Karl F. Meyer, Ph.D., Hooper Foundation, University of California, San Francisco. Dr. Parran heads a committee on public health which will give aid in time of epidemics; members are Drs. Don W. Gudakunst, state health officer of Michigan, Lansing, and George H. Ramsey, health commissioner of Westchester County, White Plains, N. Y. Dr. Peet is chairman of a committee on education with Dr. Abell and Dr. Morris Fishbein, Editor of *THE JOURNAL*, Chicago, as the other members. Dr. Lewin is chairman of a committee on treatment of after-effects; other members are Drs. George E. Bennett, associate professor of orthopedic surgery, Johns Hopkins University School of Medicine, Baltimore; Charles Leroy Lowman, Los Angeles Orthopedic Hospital, Los Angeles; Leo Mayer, associate professor of clinical orthopedic surgery, Columbia University New York Post-Graduate Medical School, New York, and Frank R. Ober, assistant dean and clinical professor of orthopedic surgery, Harvard University Medical School, Boston. The foundation has adopted the policy of assisting in study and research on the medical problem as a whole and not of giving individual care for those afflicted. It is felt that the problem of locating crippled children and providing medical, surgical, corrective and other services and care and facilities for diagnosis, hospitalization and after-care of the individual case is essentially a local problem and that the foundation must confine itself to aiding institutions and centers in which methods or procedures may be developed which will be of benefit to all the afflicted.

A Criticism of Tonsillectomy

At the Royal Society of Medicine Dr. J. Alison Glover, medical officer of the ministry of health, read a paper on the incidence of tonsillectomy in school children, in which he said that the rise in the incidence of tonsillectomy was one of the major phenomena of modern medicine. It had been estimated that 200,000 tonsillectomies were performed annually in this country and that the operation accounted for a third of all the operations with general anesthesia performed in the United States. About 1902 a rapid rise took place in the number of tonsillectomies performed in England. The period of highest incidence was at the ages of from 5 to 7 years, a time of great change in the oral cavity and in the general development of the child. Was it not possible that many of the operations performed at this period removed tonsils which were enlarged physiologically or in immunologic response to the unaccustomed herd infections of school life or to the sepsis from decay of the primary dentition? Might not some of the improvement attributed to the operation be due to physiologic changes which normally took place at this period? A study of the operation rates in different localities of this country showed wide variations but no correlation with such factors as overcrowding, poverty, bad housing or climate. The distribution defied any explanation save that of medical opinion on the indications for operation. Large and in some cases drastic reductions in the number of operations performed on elementary school children in certain areas had no unsatisfactory results. The social distribution was yet more of an enigma; tonsillectomy was at least three times as common in the well-to-do classes. The better the opportunity for careful nurture, the more the child was liable to tonsillectomy. In the public schools picked athletes had been tonsillectomized in the same proportion as other boys.

Though tonsillectomy was always something of a gamble, in certain cases it gave brilliant results. Unfortunately the recollection of these often led to operation without adequate cause or sufficient regard to the possibility of the enlargement being temporary, physiologic or immunologic. Mr. T. B. Layton, surgeon to the throat department, Guy's Hospital, had pointed out that the mortality of the operation was higher than was generally appreciated. Dr. Glover concluded by quoting from the recent report of the schools epidemic committee of the Medical Research Council: "It is a little difficult to believe that among the mass of tonsillectomies performed today all subjects for operation are selected with true discrimination, and one cannot avoid the conclusion that there is a tendency for the operation to be performed as a routine prophylactic ritual for no particular reason and with no particular result."

In the discussion there was general agreement with Dr. Glover's views. Mr. T. B. Layton said that he first adopted a conservative attitude in 1911, which further experience had strengthened. He refused to admit that the function of the tonsil was unknown; it was the largest and most important of the protective subepithelial lymphatic glands. If a person had three attacks of tonsillitis which seemed to be due to organisms residing in the tonsils he would not admit that tonsillectomy was a gamble, but otherwise he did not think that one could ever be certain that it was productive of good results. Irreparable harm could be done by removing the lymphoid tissue of children living under bad hygienic conditions.

Preventable Foot Trouble

A resolution was passed by the West Sussex Division of the British Medical Association asking that the attention of the minister of health be drawn to the large amount of preventable

foot trouble caused by the wearing of ill shaped shoes. This in turn came before the public health committee of the association and led to some discussion. It was agreed that there was good ground for some action, and one or two members urged, especially in view of the national campaign for physical fitness, that a considered and authoritative report be drawn up pointing out the damage done to the feet from the cause indicated, and that such a report should have all the publicity possible. But some cynics on the committee expressed doubt as to whether women in particular could ever be persuaded to wear proper and hygienic shoes. They did not want them, one member declared, and preferred high heels and the pattern generally worn as being really more comfortable. The opinion had been expressed in the *British Medical Journal* that it was erroneous to suppose that the shoe with the high heel had any pernicious effect and that it was rather an advantage. But the general feeling of the committee was that something ought to be done in the way of compiling a considered report. It was mentioned that through the action of the medical profession in years gone by tight lacing had disappeared. In some districts already, where there were special foot clinics, action had been taken to deal with the problem of proper footwear. Ultimately it was decided to refer the subject to the science committee of the British Medical Association.

The Use of Radium

In the eighth annual report of the National Radium Trust and Radium Commission for 1936-1937 it is stated that the outlook of surgery is rapidly altering with regard to those sites in which radiotherapy has a field of application. The previous practice of routine operation with radiotherapy as a reserve for recurrences has been virtually abandoned in the best centers. Schemes of treatment are evolved after consultation between the surgeon or laryngologist and the roentgen ray or radium therapist before anything is done. In this treatment each member of the team works on a settled plan with great advantage. The commission holds that to secure a reasonable standard of service for the treatment of cancer throughout the country the whole problem should be attacked by the government along national lines, for in only a proportion of cases suitable for radiotherapy is it being received. Every step should be taken to encourage persons suffering from or suspected to be suffering from cancer to resort to treatment at the earliest possible moment. The work done at the national centers is good but does not cover the whole country; new centers and the expansion of the existing ones are necessary.

THE DANGER OF IRRADIATING PRECANCEROUS GROWTHS

It is apt to be forgotten that radiation may produce as well as cure cancer. In the report of the pathologic research department of the Radium Institute further investigations into the treatment of precancerous lesions are reported. It had already been demonstrated that when from 4,000 to 8,000 roentgens is applied to a precancerous lesion of the skin in mice, produced by painting with tar, the onset of malignancy is delayed or even inhibited. Investigations have now shown that smaller doses, from 160 to 1,440 roentgens, increase instead of inhibiting malignancy. This indicates a serious danger in treating precancerous lesions by radiation. No doubt good results would follow if the whole lesion was given a dose of about 6,000 roentgens, but if the lesion was given a smaller dose or if any part of it received a smaller dose there would be a danger of producing cancer. During the summer it was observed that mice painted with carcinogenic agents, such as tar, shale oil or benzpyrene, when placed in the sun showed signs within a few minutes of being burned by it. Further investigation showed that these agents had sensitized the skin to light and that this action was a common property of carcinogenic agents.

Air Raid Precautions in Factories

All possible precautions are being taken in this country against the horrors of the latest development of "civilized warfare." At a meeting of the Association of Industrial Medical Officers Dr. N. W. Hammer, medical officer to the air raids precaution department of the government, said that factories should prepare plans to deal with their own special conditions, within the scheme of the local authorities for dealing with air raids. First aid parties in a factory should consist of three men, and the proportion should be two parties for 250 men, with an additional party for each additional 250 men or part thereof. The first aid parties should work with rescue parties ready to give aid before sending the victim to the first aid post or hospital. The members should be trained to relieve suffering and to save life, if the need arises, by arresting urgent hemorrhage or treating asphyxia from electrocution. A factory of any size should make provision for the reception and treatment of those injured in an air raid as a preliminary to their being sent home or to a hospital. The factory should also provide for the cleansing of the uninjured and contaminated. It might be well to have a medical officer at the first aid post to give interim treatment, including transfusions.

The Supply of Synthetic Drugs in Wartime

In the House of Commons a member asked the government whether their attention had been drawn to the fact that in war the British Empire would be without important chemical compounds of which Germany had a practical monopoly. The minister concerned replied that they were well aware that the discovery of new chemical compounds of certain kinds, particularly those used in the treatment of tropical and some other diseases, at present depends largely on research work undertaken by German industrial concerns. For this reason the government approved the proposal of the Medical Research Council for expenditure of \$150,000 per annum on research in chemotherapy, to enable this country to play a greater part in future in making new discoveries in this field.

Culture of Virus of Measles

At the May 24 meeting of the Académie de médecine of Paris a paper was read by Dr. Harry Plotz of the Pasteur Institute on the results of his study of the virus of measles. He stated that the only animal which has thus far been found susceptible to contracting measles is the monkey (*Macacus rhesus*). There is a lack of uniformity in the symptoms following inoculation of defibrinated blood taken from a given human being with measles. In a series of inoculated monkeys the Koplik sign, mucosal and cutaneous eruptions, fever, leukopenia and lymphocytosis can all be found, but rarely all of them in a single animal. The most constant are acute leukopenia and a cutaneous eruption. In a former communication Dr. Plotz called attention to a form of measles (*rougeole inapparente*) in monkeys without apparent signs. The acute leukopenia appears, as do all the aforementioned clinical evidences of the infection, after a period of incubation varying from twelve to fifteen days. If a second monkey is inoculated with the blood of one who has shown only acute leukopenia, a typical eruption is to be observed. The blood used in all the experiments was taken from a patient with measles in the service of Prof. André Lemierre at the onset of the eruption. The blood was defibrinated and 5 cc. injected subcutaneously into a monkey. The remainder of the blood was employed for cultures. Thirteen days after inoculation of the monkey, a few maculopapular areas appeared on the face and trunk. The eruption became more diffuse on the fourteenth and fifteenth

days after inoculation and disappeared completely on the sixteenth day. There was a drop from 15,500 to 5,500 in the number of leukocytes on the fourteenth and fifteenth days, the number rising gradually to normal during the next few days. The leukopenia was accompanied by lymphocytosis. There was a marked rise in temperature between the ninth and the sixteenth day. Blood taken from this monkey on the fifteenth day was inoculated into a second monkey, and a typical eruption and leukopenia followed.

The cultures of the virus are made in the presence of living cells, the technic followed being the same as that used for the culture of other viruses. Five cc. of Tyrode's solution and several drops of a suspension of chick embryo cells are placed in a 50 cc. Erlenmeyer flask for ten days. Then 1 cc. of the serum of a noninoculated monkey and 1 cc. of defibrinated blood from a patient with measles are added. After a few drops of chicken plasma are added, the flasks are closed with rubber corks. Under these conditions a culture is obtained in the presence of proliferating cells. The rubber corks are employed to prevent liberation of carbon dioxide and maintain a more uniform p_{H} concentration. The cultures are placed in an incubator at 37 C. for three days and then flasks containing the freshly prepared medium inoculated with 1 cc. of the preceding culture, previously ground in a mortar. A temperature chart was shown of a monkey inoculated with 5 cc. of a culture which had been reinoculated ten successive times on the medium cited. A typical eruption appeared on the monkey's face and trunk; it became quite diffuse as early as the first day and paler on the second day and then disappeared completely. There was a sudden drop of the leukocyte count from 22,500 to 7,500 in twenty-four hours on the eighth day. Marked lymphocytosis was noted during the period in which the eruption was most diffuse.

Treatment of Cerebral Abscess

The neurologic surgeon Dr. Clovis Vincent, in a paper at the May 4 meeting of the Académie de chirurgie of Paris, stated that poor results in a certain proportion of cases are due to the fact that one is apt to employ a more or less routine method independent of the cause of the abscess. A sharp distinction should be made between abscesses which are secondary to nasal or aural foci and the type of abscess seen by the neurosurgeon. The former as a rule are in close proximity to the primary focus, are superficial and relatively small and are not accompanied by diffuse edema of a lobe of the cerebrum. Such postnasal or postaural abscesses usually can be successfully treated by simple drainage, provided the arachnoid space is excluded, as suggested by Lemaitre. The abscesses which the neurosurgeon encounters are large, usually multilocular and multiple. They are also relatively deeply located beneath the convexity of the cerebral hemisphere. The infection reaches the brain by way of the blood stream, and the lesion is accompanied by considerable edema. Clinically, a cerebral abscess of nonotitic or nasal origin may fail to cause any symptoms, or either the picture is that of acute encephalitis or there is a history of such a syndrome. Dr. Vincent has been successful in some cases in following the method proposed by Dandy; viz., adequate exposure without opening the dura mater and simple puncture. In the majority of Dr. Vincent's cases, however, this method had been unsuccessful. The technic now employed by him consists in removal of a large portion of the wall of the abscess cavity, a procedure analogous to that used in the treatment of a cerebral neoplasm, followed by closure without drainage. If too short an interval has elapsed since recession of the symptoms referable to the primary focus, one should be content to limit the operative intervention to the construction of an osteoplastic flap over the abscess area, without opening the dura, and should carry out the complete removal of the wall and contents of the abscess

as a second step. Dr. Vincent warned against waiting too long to perform the second operation, because the wall of the abscess cavity increases rapidly in thickness, rendering its removal very difficult.

Vaccination Against Diphtheria Made Obligatory

Reference has been made to obligatory vaccination of all French soldiers against diphtheria with the aid of the Ramon toxoid, termed anatoxin here. Some time ago the lower house of the national legislature passed a bill extending such compulsory vaccination to all children during the second or third year. At its June 2 session the French senate passed a similar bill, so that such vaccination is now obligatory. Parents or guardians are made responsible for having all children vaccinated against diphtheria. No child can be admitted to any school without presenting a certificate showing that this law has been complied with. All school children up to the age of 14 years who have not previously been vaccinated must submit to vaccination as soon as possible after publication of the law in the *Journal officiel*. Publication took place June 3. The vaccinations with the aid of the Ramon toxoid will be carried out without expense to the parents. The outlay will be amply compensated by a marked reduction in the present mortality rate from diphtheria of 2,000 deaths and in the morbidity rate of over 20,000 cases annually.

Celebration in Honor of Professor d'Arsonval

The leading medical society of France, the Académie de médecine of Paris, devoted its June 7 meeting to the celebration of the fiftieth anniversary of the election to its membership of Professor d'Arsonval. Before bestowing a medal, Prof. Fernand Bezançon, president of the Académie de médecine, eulogized the many important contributions to science by Professor d'Arsonval. During a demonstration given by the physiologist Claude Bernard in 1873, d'Arsonval as a young medical student volunteered to repair a galvanometer which had failed to function during the experiment. This attracted the attention of Bernard, who asked d'Arsonval to become an assistant in his laboratory. He continued in this capacity until the death of Bernard. At this period biology and physics were considered to bear little relation to each other, and d'Arsonval devoted all his energies to demonstrating that this was not true. After Bernard's death in 1878 the young assistant d'Arsonval continued to work with Brown-Séquard until 1887, when the title of professor was bestowed on him. This period was the most fertile in the field of biophysics for d'Arsonval. His research studies on animal heat, electrophysiology, calorimetry and respiration were all published during this period.

D'Arsonval became the successor of Brown-Séquard on the latter's death in 1897 and continued to add to his already important contributions. Among these may be mentioned the perfection of many types of apparatus, such as galvanometers, calorimeters, galvanoscopes, chronometers and photometers; the description of the mechanism of contraction of muscles; the production of electricity in certain species of fishes; the discovery of the effect of electric currents on animals, and, above all, the discovery that high frequency currents can traverse the human body without damage to the tissues. The last-named contribution has been of the greatest importance in the development of modern therapeutic methods. One of the first applications of a discovery of d'Arsonval in medicine was the use of electrocoagulation in the treatment of bladder tumors. Since then the use of diathermy in the treatment of various diseases and more recently of the radio knife in surgical procedures and of transurethral resection of the prostate have greatly extended the field of application of d'Arsonval's discoveries.

At the close of the address by Professor Bezançon, d'Arsonval, who is still active at the age of 87, spoke for half an hour.

BERLIN

News of the Universities

While news of the universities was reported in *THE JOURNAL* April 11 several important new developments have occurred since then. Dr. Scheel, national fuhrer of students, recently addressed the professors and docents of Hamburg University. He said that the university must become better integrated in the Nazi state; if this long overdue adjustment is not soon made, the university itself, despite its great tradition, will face a critical situation. Today some 20 per cent of the student population belong to Nazi party formations; this proportion is far too small. Even more necessary than the "orientation," as he called it, of the students toward the new principles is a similar adjustment on the part of the faculty members. Learning is not yet sufficiently Nazi, but it must become so if the university wishes to survive. Dr. Scheel also referred to the problem of the shortage of younger men trained in the professions. For example, each year for one man graduated by a school of engineering three engineers die. If the university cannot meet the demand for trained men, industry and government will have to undertake the training of the younger generation. Such an eventuality would mean, however, the extinction of the university.

Scheel's utterances serve to illuminate many aspects of the situation. On the other hand, it is interesting to note that the national minister of education is striving to aid those smaller universities which, because of the general decline in academic matriculation, had almost been forced to close. The ministry has repeatedly stated that the maintenance of the small university is of vital importance to the state. Official efforts are being made to persuade the student to enter the smaller institutions; the principal advantages alleged are the cheaper cost of living in the smaller community as contrasted with the big city and the greater opportunity for contact between pupil and teacher. It is pointed out that the ratio of docents to students at Berlin is 1:9.3 and at Munich 1:12.5, whereas at Marburg it is 1:6.3 and at Giessen 1:3.3. The ministry refutes the objection that the academic standards and scientific equipment of the smaller universities are inferior. It is denied that the most distinguished professors are to be found only in the big cities. Material inducements too, in the form of special offers of part time employment for undergraduates, are calculated to make the small university more attractive to prospective matriculants. It is too early to determine with what measure of success, if any, these efforts have been rewarded.

Of further interest are several new regulations. The legal status of the university professor has been regulated anew. Full professors are no longer retired but are "released" (namely, released from official duties); they continue to receive their salaries but are ineligible for any further increases. The so-called lecture-guaranty, namely, assurance of a specified minimum income from lecturing, is abolished by the new plan. In a general decree the national minister of education has defined the extent of academic activity of the "released" professor. The latter retains his erstwhile official title with the added designation "emeritus." Even after being "released" a professor may be retired on account of political or racial reasons or for professional incapacity; this would entail a reduction of his salary. Furthermore, it is now stipulated that a professor can no longer be transferred by order of the ministry. Previously the new régime had decreed that professors might be transferred and retransferred even against their will; this usually signified relegation to a smaller university. This is now changed. The age limit remains, as for all other government employees, at 65. Previously the compulsory retirement

age of professors was not uniform throughout the reich; in many German states it was fixed at 68, in many others at 70, and so on. Another order, issued by the national minister of education, deals with the award of honorary academic degrees. The new law supersedes all former regulation of this custom. Henceforward the candidate for an honorary degree must measure up to strict professional and personal qualifications. The minister reserves to himself the right to examine any candidate. This greater discrimination can only be most welcome. During the postwar period the conferring of honorary degrees became common, and often purely financial considerations were involved. One might say that at certain institutions the doctor's degree *honoris causa* could be purchased for a price. In the future, distinguished personal contributions to knowledge will be the only recognized qualification for the honorary doctorate. No longer will degrees be conferred for indirect services, such as the establishment of foundations and other gifts by industrial magnates. Nor will noteworthy and nonscientific contributions to the state by men in public life any longer be rewarded by the honorary doctor's degree. Members of the Nazi party may now receive the honorary doctorate, but they must offer the same scholarly qualifications as other citizens. University professors on active service cannot receive the honorary doctorate. German citizens who are candidates for honorary degrees must qualify under the usual racial and political tests. A special authorization from the minister will be required for the conferring of the degree on a foreigner. Bestowal of the honorary title of senator, citizen or president by a university is regulated in general by the mentioned provisions, except that these titles may be conferred in recognition of indirect service to learning, such as the establishment of a foundation.

Measures have been taken to integrate Austrian universities into the Nazi system. These schools are now to form "the living bridge to the peoples and provinces of the southeast." The matriculation of Jewish students has been further restricted; the quota of Austrian Jews permitted to study at the university at any one time is fixed at 2 per cent in each special field. This percentage is somewhat smaller than the proportion of the Jewish to the total population of Austria, for, as stated in the ministerial decree, this establishment of a *numerus clausus* is calculated to offset a development that has been going on for decades. In the winter semester of 1936, 11 per cent of the student population of Austrian universities were Jews, namely, members of the Jewish religious group. At Vienna University alone the percentage of Jewish students was 19.42, and in the medical school about one third of all matriculants were of Jewish extraction. The following data on enrolment in the Austrian universities attest the importance of these institutions in the academic world: The number of students of all Austrian schools of university rank, including the veterinary and business institutes, is more than 15,000, whereas in the older German reich, with ten times as great a population, the number of university students is around 75,000, only five times the number of Austrian students. Of the 15,000 students in Austria a good 25 per cent are women. The enrolments at the various universities are 9,900 students at Vienna, barely 2,000 at Graz and 1,500 at Innsbruck. About 4,500 students are matriculated in the medical schools; this is the largest number in training for any one profession.

Group Examinations for Cancer

The professor of gynecology at Königsberg recently reported examinations at his clinic for cancer. Women of 30 and over are subjected to gynecologic examinations at definite intervals. These examinations are made to determine whether pathologic conditions exist. The women receive further consultation where the treatment is actually given. The group examinations are made only to promote the early diagnosis of cancer. Difficulties which were encountered at first in inducing the women to sub-

mit to this examination have now been overcome. In the course of 2,587 examinations of this type, eighty-one erosions suggestive of carcinoma were detected, that is, in 3.1 per cent of the examined women. In 25 per cent of these eighty-one cases of suspected erosion, the exploratory excision disclosed a carcinoma. Moreover, three carcinomas of the uterine cervix and one carcinoma of the rectum were detected among the 2,587 women. At the same time, these group examinations revealed that myoma is to be found at the most in 2 per cent of women who have passed the age of 30. In general it may be said that group examinations provide possibilities for the early diagnosis of carcinoma which are not available otherwise.

AUSTRALIA

(From Our Regular Correspondent)

May 24, 1938.

National Health Insurance Scheme

A bill for national health and pensions insurance, now being debated in the commonwealth parliament, will if it becomes law materially affect medical practice in Australia. Although the great advances made in prevention and treatment of disease in the last fifty years have increased the cost of satisfactory medical service, many are of the opinion that a plan involving impersonal payment will interfere with the personal relationship which must exist between patient and doctor. Inadequate payment will destroy this relationship, and if a practitioner must take too many patients in order to make a reasonable living he cannot cultivate that personal contact or spend the necessary time to do the good work. The federal council of the British Medical Association in Australia has agreed on a remuneration of 11 shillings per unit yearly. Whether this will prove adequate cannot be determined until the scheme has been in operation for a time. The government's present proposals for health insurance were described as incomplete and inadequate in an official statement issued by the federal council of the British Medical Association. The association considers that the essential principles which should form the basis of any national health service are that the service should offer full scope and opportunity for the prevention and cure of disease and the promotion of full mental and physical activity; that the service should offer opportunities for research, without which there can be no advance in medical or public health; that the service should be based on the provision of a general practitioner of his own choice for every individual, in accordance with the present system of private practice; that the service should be complete—not only must it provide to every one the services of a general practitioner, but it must make available consultant and specialist services and such auxiliary services as pathologic and x-ray examinations, nursing and massage services. There must also be accommodation and treatment in hospitals, sanatoriums and convalescent homes.

The present proposal embraces only a section of the community, about 1,850,000 of the workers, and does not include their dependents, and it makes no provision for the unemployed or the unemployable, many of whom are in the greatest need of medical attention. It does not supply a specialist or an institutional service. It ignores preventive measures and takes no account of the greatest medical need of the day, a vastly increased provision for early diagnosis of disease. The government's scheme is, in effect, an extension of the system of contract practice by which members of friendly societies receive medical benefits. The friendly societies are vitally interested in the scheme. They at present cater to 600,000 members and their dependents in Australia, and of these it is estimated that 400,000 will come under the new scheme. Their organizations could be of great assistance to the authorities in the administration of the scheme, because of their long experience with sickness benefit. However, friendly societies as such will receive no par-

ticular recognition from the scheme. They may form approved societies for administration of a section of medical benefits, but this advantage is offered to any organization with a membership of 2,000 or more. The loss in the friendly societies' voluntary membership will probably be considerable. As the national scheme makes no provision for dependents, it is expected that the friendly societies will come to some agreement with the medical profession for voluntary insurance against contingencies affecting dependents.

There are still many important details of the bill to be discussed, among them being the form of administration, the problem of the sparsely populated areas, the question of mileage and the definition of the scope of a general practitioner service. In all these matters, representatives of the profession are to be consulted. Other matters of great importance are cooperation between the national health insurance service and the hospital service in each state, the organization of a medical service for dependents, the organization of a medical service for the unemployed and cooperation with the dental profession.

Australian Consumption of Sugar

In spite of continuous efforts of members of the medical profession and others interested in the nutrition of the community to reduce the consumption of cane sugar and other highly refined carbohydrates in Australia, the figures of the sugar board for the 1937 season show a further increase in home consumption. The season showed a record output of 810,000 tons, compared with 782,000 in 1936 and 647,000 in 1935. Of the total purchased, 365,000 tons, or 45 per cent, was used by Australia, representing an average per capita consumption of 121 pounds (55 Kg.) per annum, or 0.33 pound (151 Gm.) daily. The position in Queensland is interesting. The Queensland Nutrition Council energetically condemns large amounts of sugar or sweet foods in a diet which attempts at balance, contending that, although sugar in itself is not harmful, it destroys appetite for the more wholesome foods. On the other hand, this state produces over 95 per cent of Australian sugar, and the industry has played an important part in the development of tropical areas.

The White Australia policy forbids the use of colored labor on the canefields, with the result that there is a large white population working under humid, tropical conditions and presenting nutrition problems of its own. The Queensland Nutrition Council is anxious to assist in the solution of these problems and has received promise of financial support from the Australian Sugar Producers' Association. It should be interesting, therefore, to watch the consumption of sugar in Queensland for the next several years.

Marriages

THEODORE C. ERICKSON, Montréal, Que., Canada, to Miss Mary Rachel Harrower of Cheam, Surrey, England, May 24.

GENEVA M. DYE, Washington, D. C., to Mr. Joseph Turner of Lurgan, North Ireland, in Hong Kong, China, in April.

FRANCIS JAMES BRACELAND to Miss Hope Van Gelder Jenkins, both of Philadelphia, June 1.

DOROTHY LOOMIS FRAME, New York, to Mr. Charles Billings England of Passaic, N. J., May 28.

PAUL E. McMASTER to Miss Anna E. La Chapelle, both of Los Angeles, May 28.

MILTON L. MILLER, Chicago, to Miss Bernice Saul of New York, May 6.

MAURICE GERSHMAN to Miss Belle Kalikow, both of Brooklyn, April 3.

JAMES THOMAS KING to Miss Martha Foster, both of Atlanta, Ga., June 7.

Deaths

Frank Alexander Delabarre, Boston; University of Pennsylvania Department of Medicine, Philadelphia, 1895; also a dentist; assistant professor of orthodontia, 1907-1910, professor, 1910-1918, Tufts College Dental School; chief of staff orthodontia department and dean, Postgraduate School of Orthodontia, Forsyth Dental Infirmary for Children, 1914-1919; consultant, Massachusetts Department of Health; lecturer, Tufts College Dental School, and Harvard University Dental School; past president of the Massachusetts Dental Society, American Academy of Dental Science and the New York Society of Orthodontists; president-elect of the American Association of Orthodontists; aged 70; died, April 16, in the Faulkner Hospital.

Sandford Halsey Kinne, Binghamton, N. Y.; Syracuse University College of Medicine, 1909; member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; otolaryngologist to the Binghamton City and Lourdes hospitals and Charles S. Wilson Memorial Hospital, Johnson City; consulting otolaryngologist to the Binghamton State Hospital, Ideal Hospital, Endicott, and the Tioga County General Hospital, Waverly; aged 53; died, April 13, of nephritis, hypertension and cerebral thrombosis.

William Frederic Moore * Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1905; assistant professor of bronchoscopy and esophagoscopy at the Graduate School of Medicine of the University of Pennsylvania; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Bronchoscopic Society; on the staffs of the Philadelphia General, Episcopal and Children's hospitals; served during the World War; aged 56; died, April 25, of heart disease.

William John Steele, Baldwin, N. Y.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; member of the Medical Society of the State of New York; on the staffs of the Nassau Hospital, Mineola, and the Mercy Hospital, Hempstead; formerly member and president of the board of education; bank president; for many years postmaster; aged 70; died, April 21, of diabetes mellitus, pyelonephritis, coronary sclerosis and lobar pneumonia.

R. Decatur Smith, Greenville, S. C.; University of the South Medical Department, Sevanee, Tenn., 1897; Medical College of the State of South Carolina, Charleston, 1902; member of the South Carolina Medical Association; past president of the Greenville County Medical Society; aged 67; died, April 19, in the General Hospital of toxemia due to burns received from a gas heater.

William Orlin Colburn * Lincoln, Neb.; Northwestern University Medical School, Chicago, 1904; member of the American Academy of Pediatrics; past president of the Lancaster County Medical Society; chairman of the department of pediatrics, Bryan Memorial Hospital; aged 57; died, April 10, of coronary occlusion, nephrolithiasis and pyonephrosis.

Eugene Gates, Two Rivers, Wis.; Rush Medical College, Chicago, 1902; member of the State Medical Society of Wisconsin; aged 67; past president and secretary of the Manitowoc County Medical Society; served during the World War; aged 68; on the staff of the Municipal Hospital, where he died, April 28, of cerebral hemorrhage and arteriosclerosis.

Alfred Lubbert Van Dellen * Chicago; Northwestern University Medical School, Chicago, 1910; member of the American Academy of Ophthalmology and Oto-Laryngology; on the staffs of the Illinois Eye, Ear, Nose and Throat Infirmary and the Englewood Hospital; aged 50; died, April 1, at Rochester, Minn., of ureterolithiasis.

Norman L. Howison, Menomonie, Wis.; State University of Iowa College of Medicine, Iowa City, 1882; for many years county physician and health officer of Menomonie; for thirty years attending physician to the Dunn County Asylum and County Home; aged 88; died, April 1, of a fracture of the hip received in a fall.

Paul Carroll Lybyer, Ogdensburg, N. Y.; Rush Medical College, Chicago, 1914; member of the Medical Society of the State of New York and the American Psychiatric Association; served during the World War; aged 52; on the staff of the St. Lawrence State Hospital, where he died, April 23, of chronic myocarditis.

Walter Spencer Fleming * Mount Vernon, N. Y.; University of the City of New York Medical Department, 1884; an Affiliate Fellow of the American Medical Association; aged 74;

on the staff of the Mount Vernon Hospital, where he died, April 5, of hypertensive heart disease and cerebral hemorrhage.

Ernest Robert Middleton, Abilene, Texas; Fort Worth School of Medicine, Medical Department of Texas Christian University, 1909; aged 52; fellow of the American College of Surgeons; on the staff of the West Texas Baptist Sanitarium; aged 53; died, April 15, of coronary occlusion.

Robert Francis Morton, Staten Island, N. Y.; New York Medical College and Flower Hospital, New York, 1937; aged 30; intern at St. Vincent's Hospital, West New Brighton, where he died, April 11, of injuries received when thrown from an ambulance while speeding to a sick call.

Robert F. Gates, Brownville, N. Y.; Homeopathic Hospital College, Cleveland, 1885; for many years member of the board of education; at one time county coroner; health officer of the villages of Pamela, Brownville and Glen Park; aged 77; died, April 3, of myocarditis.

Frederick Morton Harris, Green Bay, Wis.; Rush Medical College, Chicago, 1914; formerly secretary of the Brown-Kewance-Door County Medical Society; served during the World War; aged 49; died, April 7, in the Veterans Administration Facility, Hines, Ill.

Warren Brown Keator, Findlay, Ohio; Barnes Medical College, St. Louis, 1895; member of the Ohio State Medical Association; served during the World War; formerly on the staff of the Home and Hospital; aged 72; died, April 20, of cerebral hemorrhage.

Frank Anson Smith, Lebanon, N. H.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1884; member of the New Hampshire Medical Society; aged 82; died, April 25, in St. Petersburg, Fla., of coronary occlusion.

James Harris Hicks, Denton, Texas; Barnes Medical College, St. Louis, 1899; member of the State Medical Association of Texas; formerly on the staff of the Denton Hospital and Clinic; at one time county health officer; aged 62; died, April 6, of heart disease.

John Calvin Keller * Windgap, Pa.; Columbus Medical College, 1886; past president of the Northampton County Medical Society; for many years secretary of the board of health of Windgap; on the staff of the Easton (Pa.) Hospital; aged 73; died, April 26.

Floyd Grant Patterson * Du Bois, Pa.; University of Pittsburgh School of Medicine, 1909; served during the World War; on the staff of the Du Bois Hospital; formerly on the staff of the Maple Avenue Hospital; aged 50; died, March 25, in Bradford.

Francis Aubrey Howard, Slater, Mo.; St. Louis Medical College, 1877; member of the Missouri State Medical Association; aged 84; died, April 22, in the John Fitzgibbon Memorial Hospital, Marshall, of chronic nephritis, uremia and arteriosclerosis.

Garabed Arshag Zacar Garabedian * Tulsa, Okla.; Rush Medical College, Chicago, 1913; assistant in medicine (pediatrics) at his alma mater; aged 49; died, April 26, of coronary thrombosis secondary to streptococcal infection of the throat.

Frank J. Hitchcock, Binghamton, N. Y.; University of Vermont College of Medicine, Burlington, 1890; member of the Medical Society of the State of New York; coroner; aged 77; died, April 25, in the City Hospital of coronary thrombosis.

Edgar Alexander Fisher * Worcester, Mass.; Boston University School of Medicine, 1887; fellow of the American College of Surgeons; on the staff of the Worcester Hahnemann Hospital; aged 72; died, April 18, of lobar pneumonia.

Winfield Scott Gehrett, Deshler, Ohio; Western Reserve University School of Medicine, Cleveland, 1919; member of the county board of health; aged 44; died, April 5, in the Woman's and Children's Hospital, Toledo, of coronary thrombosis.

Ellen Emma Bartholomew Scudder, New York; Cornell University Medical College, New York, 1899; formerly a medical missionary; aged 64; died, April 10, of arteriolar nephrosclerosis, cardiac hypertrophy and hypertension.

Ross Edward Anderson, Memphis, Tenn.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1931; member of the Tennessee State Medical Association; aged 39; was found dead, May 3, of a self-inflicted bullet wound.

John A. Stapleton, Rochester, N. Y.; University of Buffalo School of Medicine, 1891; member of the Medical Society of the State of New York; for many years police and fire surgeon; aged 78; died, April 13, of myocarditis and nephritis.

Harold Virgil Johnson, Fort Worth, Texas; Jefferson Medical College of Philadelphia, 1909; member of the State

Medical Association of Texas; on the staff of the Baptist Hospital; aged 50; died, April 22, of coronary heart disease.

Nicasio Gregorio Gonzalez, Kansas City, Mo.; University of Kansas School of Medicine, Kansas City, 1930; aged 34; on the staff of the University of Kansas Hospital, Kansas City, Kan., where he died, April 30, of myelogenous leukemia.

William Henry Coe @ Auburn, N. Y.; Bellevue Hospital Medical College, New York, 1896; aged 66; on the staffs of the Mercy Hospital and the Auburn City Hospital, where he died, April 6, of duodenal perforation and cholecystitis.

Donald Clare Hoffman, New York; Harvard University Medical School, Boston, 1926; an associate medical director of the Metropolitan Life Insurance Company; aged 39; died, April 21, in Rye, N. Y., of essential hypertension.

William Garfield Henderson, Cuba, Mo.; University of Louisville Medical Department, 1912; member of the Missouri State Medical Association; formerly county coroner; aged 56; died suddenly, April 19, of coronary thrombosis.

Oscar Highland Ternstrom @ Minneapolis; University of Minnesota Medical School, Minneapolis, 1920; on the staff of the Lutheran Deaconess Hospital; aged 46; died April 20, in St. Barnabas Hospital, of coronary thrombosis.

Whitfield Harral, Dallas, Texas; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; formerly medical director of the Southwestern Life Insurance Company; aged 67; died, April 12.

Robert William Bobe, Monroe City, Ind.; Washington University School of Medicine, St. Louis, 1934; member of the Kansas Medical Society; aged 28; died, April 13, in the Deaconess Hospital, St. Louis, of heart disease.

William Ira Fulton, Mount Vernon, Mo.; Missouri Medical College, St. Louis, 1897; member of the Missouri State Medical Association; served during the World War; aged 65; died, April 17, in Springfield of angina pectoris.

Walter P. McGrath, Menasha, Wis.; Milwaukee Medical College, 1903; was president of the health council, and city physician; aged 59; died, April 14, in St. Elizabeth's Hospital, Appleton, of uremia and chronic nephritis.

Russell Newton Davis, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; on the staff of the South Shore Hospital; aged 54; died, April 30, of coronary thrombosis.

Isaac N. Mayfield, Giddings, Texas; Louisville (Ky.) Medical College, 1880; member of the State Medical Association of Texas; for many years county health officer; aged 81; died, April 12, of diabetes mellitus.

Edward Philip Laskey @ Haverhill, Mass.; Harvard University Medical School, Boston, 1909; on the staff of the Haverhill Municipal Hospital; aged 55; died, April 23, of aortic stenosis and aortic regurgitation.

Haim Guelman @ New York; University and Bellevue Hospital Medical College, New York, 1910; on the staff of the Fordham Hospital; aged 58; died, April 29, in the Fordham Hospital of coronary occlusion.

William S. Grisell, Bartley, Neb.; Kansas City Medical College, 1899; formerly owner of the Grisell Memorial Hospital, Ransom, Kan.; served during the World War; aged 65; died, April 13, of influenza.

Taylor Hudson, Belton, Texas; Louisville (Ky.) Medical College, 1877; member and past president of the State Medical Association of Texas and the Bell County Medical Society; aged 83; died, April 24.

Albert Eugene Smith @ Craig, Colo.; Denver and Gross College of Medicine, 1904; served during the World War; aged 71; died in April, in the Fitzsimons General Hospital, Denver, of nephritis.

Samuel A. Gifford, Laurel, Ind.; Medical College of Ohio, Cincinnati, 1879; member of the Indiana State Medical Association; aged 82; died, April 26, of chronic hypertrophy of the heart and nephritis.

John Craig McAllister @ Ridgway, Pa.; College of Physicians and Surgeons, Baltimore, 1889; member of the American Academy of Ophthalmology and Oto-Laryngology; aged 76; died, April 18.

James Finley Leeper, McConnelsville, Ohio; Starling Medical College, Columbus, 1878; member of the Ohio State Medical Association; aged 79; died, April 22, of cerebral hemorrhage.

William Augustine Hulse, Bay Shore, N. Y.; Bellevue Hospital Medical College, New York, 1883; member of the Medical Society of the State of New York; aged 79; died, April 8.

Eva S. Shaver, Chicago; National Medical University, Chicago, 1903; aged 67; died, April 6, in the Norwegian American Hospital of hypertension and chronic myocarditis.

Thomas Linley, Cleveland; Western Reserve University Medical Department, Cleveland, 1896; aged 64; died, April 6, of cerebral hemorrhage, arteriosclerosis and hypertension.

Peter Robb McArthur, Los Angeles; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1899; member of the California Medical Association; aged 69; died, April 5.

Joseph J. Gottlob, Cleveland; Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1900; aged 69; died in April at the City Hospital.

Stark Armistead Sutton @ Norfolk, Va.; University of Maryland School of Medicine, Baltimore, 1894; formerly city health officer; aged 65; died, April 1, of pneumonia.

Ray Gifford Lawrence, Port Jervis, N. Y.; New York University Medical College, New York, 1898; aged 68; was found dead, April 4, of injuries received in a fall.

John H. Haizlip, Nederland, Texas; College of Physicians and Surgeons, Baltimore, 1897; member of the State Medical Association of Texas; aged 65; died, April 11.

Henry Bascom Shields, Carthage, N. C.; Atlanta Medical College, 1882; member of the Medical Society of the State of North Carolina; aged 85; died, April 15.

Ernest Albert Chapman, Dobbs Ferry, N. Y.; New York University Medical College, 1896; aged 76; died, April 1, of chronic pyelonephritis and myocarditis.

Edwin Robert Espie, Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1892; aged 73; died, April 25, in Weirsdale, Fla.

W. Frank Schrader, Fort Wayne, Ind.; Fort Wayne College of Medicine, 1894; aged 70; died, April 14, of hemorrhage following a gallbladder operation.

Luther L. Gilbert, Prospect Station, Tenn.; College of Physicians and Surgeons, Baltimore, 1886; aged 72; died, April 30, of aortic regurgitation.

Daniel William Lewis, Philadelphia; Jefferson Medical College of Philadelphia, 1909; aged 63; died, March 31, of cerebral hemorrhage.

Nathan R. Gregg @ Coulee City, Wash.; St. Louis College of Physicians and Surgeons, 1893; aged 64; died, April 23, of coronary thrombosis.

Lucian Mason McLendon, Dallas, Texas; Physio-Medical College of Texas, Dallas, 1905; aged 74; died, April 13, of coronary occlusion.

Robert Woodhouse Fowler, Richmond Hill, N. Y.; New York University Medical College, New York, 1897; aged 64; died, April 28.

Irving H. Edginton, Detroit; Memphis (Tenn.) Hospital Medical College, 1891; aged 68; died, April 3, of cerebral hemorrhage.

James H. Seabee, Paris, Ky.; Louisville National Medical College, Medical Department State University, 1892; died, April 16.

William Asa Smith, Glendale, S. C.; Medical College of the State of South Carolina, Charleston, 1891; aged 69; died, April 11.

Dunklin Pierce McLaurin, Jackson, Miss.; University of Tennessee Medical Department, Nashville, 1892; aged 78; died, April 4.

Berthold P. Bebee, St. Louis; St. Louis University School of Medicine, 1903; aged 57; died, April 22, of a gunshot wound.

Joseph A. Smith @ Chicago; Chicago College of Medicine and Surgery, 1909; aged 54; died, April 3, in Miami Beach, Fla.

Max Finkelstein @ New York; University of Maryland School of Medicine, Baltimore, 1916; aged 50; died, April 25.

James Moore, Trowbridge, Ont., Canada; Trinity Medical College, Toronto, Ont., 1900; died, April 10, in Listowel.

John Ballinger Eads, Lexington, Ky.; University of Louisville Medical Department, 1897; aged 67; died, April 26.

Charles Walden, Harrisburg, Ill.; St. Louis College of Physicians and Surgeons, 1909; aged 65; died, April 25.

Wesley John Reid, Detroit; Michigan College of Medicine and Surgery, Detroit, 1898; aged 63; died in April.

Robert James Liles, Tyler, Texas; Memphis (Tenn.) Hospital Medical College, 1893; aged 77; died, April 22.

Lewellyn D. Hixson, Ann Arbor, Mich.; Detroit College of Medicine, 1897; aged 65; died, April 18.

Bureau of Investigation

SOME MISCELLANEOUS MAIL-ORDER FRAUDS

For many years the Post Office Department has done splendid service in protecting the public against medical frauds that operate through the United States mails. The task is a difficult and a thankless one. Unfortunately, few newspapers and magazines publish the results of the work done by the Post Office Department. In the nature of the case, the majority of such frauds have been made possible through the carelessness or venality of some newspapers and magazines which open their advertising pages to the fraudulent concerns.

In certain instances in which the frauds have been particularly successful in a financial way the men behind them have wielded no little political influence, and cases are on record in which in the past the official positions of influential politicians have been used in the interest of the medical mail-order faker and against the work of the Post Office Department.

This department of THE JOURNAL has for more than a quarter of a century abstracted, usually in some detail, the cases of medical mail-order fraud in which, through the activity of the Post Office Department, the exploiters have been debarred from the use of the United States mailing privileges. Some of the frauds, in the nature of the case, are comparatively trivial. Others are such as to have brought the men who conduct them large fortunes. In this issue we give in brief form the essential facts regarding some comparatively small-bore medical swindles against which fraud orders have been issued recently. These miscellaneous fakes cover such fields as alleged cures for obesity, diphtheria, tuberculosis and diabetes:

DELATOL LABORATORIES.—This was a fraudulent alleged cure for diabetes that was marketed by one Frank Willard Kimball from Oakland, Calif. Kimball had also been associated with the Melatol Laboratories of San Francisco, which sold another fake cure for diabetes. In October 1935 Kimball was convicted of violating the Food and Drugs Act in connection with his activities in the Melatol Laboratories and was fined \$400. In January 1937 the Melatol Laboratories were debarred from the mails. Kimball advertised that his so-called Delatol treatment would cure diabetes. The "treatment" consisted of tablets and "Herb Tea." Government analyses showed that the tablets consisted essentially of laxatives (senna, licorice, and the like), while the Herb Tea was mainly sassafras bark, licorice root, mistletoe leaves and stems, juniper berries and mint leaves. In other words, the Herb Tea, like practically every fake cure for diabetes, was essentially a diuretic. The scheme in such cases consists in causing the patient to pass a larger amount of urine daily, so that any given specimen contains a smaller proportion of sugar, although the actual sugar excretion may be increased. Kimball was not a chemist, pharmacist or physician and had no medical training. His scheme was declared a fraud, and a fraud order was issued against the Delatol Laboratories and against Frank Willard Kimball on Feb. 24, 1938.

JOSEPH W. HOLLAND.—From Danville, Ala., one Joseph W. Holland and his two sons, Hubert and Alvin J., advertised and sold through the mails a booklet entitled "Tuberculosis and Pneumonia, Their Cause, Symptoms, Treatment and Prevention." It was represented that this booklet contained information on how to cure tuberculosis and certain other diseases. The business was started at Florence, Ala., in 1933 but later moved to Danville. Holland was formerly a school teacher. He asked \$1.25 for his booklet. There was also worked, in addition, the trick-prescription fake. Holland told his victims that "Dr. Hull's Prescription" was a good one but that only a few drug stores would carry the medicines necessary to fill the prescription. Holland offered to get it filled for \$1.50. Investigation by the Post Office authorities showed that Holland's so-called treatment was contrary to modern practices employed in the treatment of tuberculosis and in many instances would prove distinctly harmful to sufferers from tuberculosis. The Hollands had no physicians, chemists or pharmacists connected with their business and none of them had any medical training. The government declared that such an attempt by inexperienced

laymen to treat a disease as deadly as tuberculosis was a danger to the public health. On June 1, 1938, the mails were closed to Joseph W. Holland and Joseph W. Holland and Sons.

EDWARD J. McCANN AND TONSOL.—From Elmira, N. Y., Edward J. McCann sold through the United States mails a preparation that he called "Tonsol," for the alleged treatment and cure of diphtheria and tonsil infections. The business was started in 1922. When analyzed by the government chemists, Tonsol was found to be essentially a 15 per cent solution of mild silver protein (argyrol type). The danger, not only to the individual but to the community, of attempting to treat diphtheria with a spray sold on the mail-order plan, is obvious. During the hearing the postal authorities brought out the fact, well known to physicians, that in addition to diphtheria the tonsils may be the site of syphilitic ulcers and cancers and are also usually acutely inflamed in scarlet fever. Obviously, spraying such tonsils with Tonsol would be not merely ineffective but dangerous to the patient, because of the neglect of proper treatment. McCann had no medical education or training and had no one with such qualifications connected with his business. Tonsol was manufactured by McCann and his wife at their residence, despite the fact that neither of them had any education or training in chemistry or pharmacy. On Feb. 24, 1938, a fraud order was issued against E. J. McCann and Tonsol.

SLENDRA LABORATORIES.—This was another Elmira, N. Y., medical mail-order fake. Slendra Laboratories was a trade name used by Joseph H. Updyke, whose regular business was that of conducting a lunch room. In other words, Mr. Updyke seemed to work both sides of the street—he sold foods that presumably would increase the weight, and he also had some pills that were alleged to reduce weight. When analyzed in the government laboratories, Mr. Updyke's tablets were found to contain about one-tenth grain of iodine and one-half grain of phenolphthalein, with a small amount of leptandrin, corn starch, chalk and mineral oil. In common with most obesity-cure quacks, Mr. Updyke so advertised as to lead prospective victims to believe that neither dieting nor exercise was necessary in order to secure the reduction of weight promised as a result of using his Slendra tablets. After the victim had parted with his money, however, he was told that if he wished to get thinner he should not eat pork, ham, bacon, any fat meat, olive oil, butter, cream, cheese, sugar, candy, pastry, potatoes, sardines in oil or bananas; he was also told to get some exercise in the open air every day! If such a regimen were followed, the Slendra tablets could, of course, have been thrown in the ash-can and just as good results obtained. While the amount of iodine in Updyke's tablets was not sufficient to produce a reduction in weight, it might, in certain cases, produce thyroid poisoning. No physicians, chemists or pharmacists were connected with Mr. Updyke's business, and in the government report on the case it seems that Mr. Updyke cynically admitted to the Post Office Inspector who investigated the case that he did not think that Slendra would cure obesity. On March 16, 1938, the Slendra Laboratories were debarred from the United States mails.

WEIGHT CONTROLS

Cataracts Develop Following Use of Anti-Fat Nostrum

In spite of the warnings from the medical profession and public health officials against the use of secret remedies sold for the alleged reduction of weight, products of this type continue to take their toll. During the past year the Bureau of Investigation has received reports from physicians of serious results following the use by patients, on their own responsibility, of a piece of mail-order quackery sold as a "fat cure" under the name of "Weight Controls." The product, which is reported to come in capsule form, was sold by Weight Controls, Inc., House of Health Building, 33 West 47th Street, New York City.

From tests made in October 1937 by the A. M. A. Chemical Laboratory of the contents of some of the capsules sent in by physicians as being Weight Controls, it appeared that the active ingredient of this nostrum was either dinitrophenol or a closely allied substance, dinitrocresol.

Dr. J. J. Hanna of Quanah, Texas, reported the case of a 21 year old woman who came to his office complaining of

poor vision. She was overweight and for four and a half months she took capsules which she said she purchased from Weight Controls, Inc. These reduced her weight some 46 pounds, but her vision was reduced to light perception in the right eye and 20/200 in the left, and that eye failing fast.

The State Medical Society of Wisconsin reported that Dr. E. E. Neff of Madison, who had been cooperating with the society in making a study of cataract cases resulting from the use of reducing capsules, reported the case of one cataract patient who had allegedly used a product sold and distributed by Weight Controls, Inc.

Dr. Alton V. Hallum of Atlanta reported that he had a patient who claimed to have taken two boxes of Weight Controls capsules, lost about 25 pounds weight and in a few months developed bilateral cataract.

Drs. Dodd and Hamner of Petersburg, Va., reported the case of a patient who allegedly took Weight Controls and developed cataract and became totally blind in both eyes within twelve days.

Dr. J. B. Nail of Wichita Falls, Texas, has reported the case of an obese young woman who came to him for examination, complaining of loss of vision. She was found to have bilateral cataract and gave a history of having taken Weight Controls.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACTIVITIES OF CHILD HEALTH COMMITTEE IN COUNTY MEDICAL SOCIETY

To the Editor:—Have you any information of value in line with the activities of a child health committee of a county medical society? I will greatly appreciate any suggestions you have to offer.

C. HAYDEN PHILLIPS, M.D., Wilkes-Barre, Pa.

ANSWER:—These activities might include the following, or as many of them as are appropriate in a local situation:

1. The community water supply and its relation to sewage disposal and other sanitary questions should be studied. A safe water supply is a fundamental necessity for a satisfactory state of child health, since advice to boil water before feeding to infants is not universally followed among ignorant mothers.

2. The source, handling and distribution of the community milk supply should be studied, with particular reference to availability of fresh pasteurized milk from tuberculin tested herds, delivered in properly capped bottles. A safe milk supply is fundamental for satisfactory child health conditions and it is generally agreed that minimum requirements are tuberculin tested herds, clean barns and milk houses, clean, healthy workers, clean utensils, prompt cooling and delivery of milk, pasteurization (except certified milk) and bottling.

3. Investigation should be made into the availability of health supervision for well babies for all classes of the population, each at an appropriate price. This means that families which can pay for supervision of their own babies should do so through appropriate relationships with private physicians of their own choice, but it also means that provision must be made for similar care for those unable to pay. If this problem is faced and solved by the medical society, there will be no occasion for other community groups to put forward solutions of their own which may be inequitable or otherwise unsatisfactory.

4. Provision should be made in the community, through health department or county medical society channels or jointly, for a constant program of parent education with relation to health. This would include use of the radio, if available, and of newspapers, pamphlets, physician speakers and other methods, such as the occasional use of exhibits and motion pictures.

5. Provision should be made through the offices of private physicians, or by other means worked out cooperatively between the health department and the local medical profession, to insure immunization against smallpox, diphtheria and perhaps whooping cough, during the first year of life for all children. As stated before, financial arrangements should be appropriate to the financial capacity of the family; but, whether pay or free, the work should be done wherever possible through the office of a physician chosen by the family.

6. The community hospital facilities for children should be studied and inadequacies or inequalities, if any are discovered, should be called to the attention of the community with appropriate suggestions for remedial measures.

The following material has been published by the American Medical Association Bureau of Health and Public Instruction, dealing with the relationship of physicians to the public health program both as regards relationships with public health officials and in connection with their public health and health education responsibilities. It will be sent free on request to physicians:

OBLITERATIVE PLEURITIS IN PULMONARY TUBERCULOSIS

To the Editor:—What is the etiology of obliterative pleuritis occurring during the course of artificial pneumothorax for pulmonary tuberculosis? Is it necessarily progressive? If so, how long would it take for the pleural cavity to become obliterated if the degree of pulmonary collapse is about 75 per cent? Assuming that the process began with the formation of fluid (hydropneumothorax) would the spontaneous disappearance of the fluid retard the progress of the disease? If the pleural cavity should become completely obliterated, would the lung necessarily reexpand completely? Does the process give any information regarding the underlying parenchymatous lesions? What is the ultimate prognosis? What is the treatment?

M.D., New York.

ANSWER:—This condition is caused by a combination of factors, the most important of which is fluid in the pleural cavity, usually caused by infection. The quality of fluid is important. Simple transudates are rather easily resorbed without any after-effects; but serous exudates, particularly those caused by infections with the tubercle bacillus, are prone to cause the pleural surfaces to adhere on resorption of the fluid. An added factor is the content of fibrinogen. The more fibrinogen present the heavier will be the clot and in turn the quicker will be organization by fibrosis. Any acute purulent infection that tends to destroy this "grundlage" of fibrosis will militate against obliterative fibrosis. The mechanism is chiefly an irritation of a surface of the pleura in the region of a tubercle; then a lymph node or other obstruction prevents a return flow of lymph toward the hilus of the lung and this is followed by the accumulation of fibrinous exudate, as mentioned. First, a fibrinous exudate forms between the pleural layers, which undergoes a monocytic infiltration, followed by fibroblasts and capillaries (granulation tissue) and ultimately fibrous tissue; second, adhesion of the two layers may take place without the fibrinous exudate, but in such cases the two layers are "semidry." They usually have previously undergone varying degrees of inflammation, most commonly by the tubercle bacillus. In the latter instance it is a "creeping" process. The new fibrous tissue draws in new pleural surfaces and continues on till the whole cavity is frequently obliterated by thin "spider-web" adhesions.

The time required to obliterate a cavity 75 per cent collapsed is variable. If proper collapse is kept up it need not become obliterated at all. Occasionally the "creeping" type will obliterate any cavity in periods ranging from two to four months. The spontaneous disappearance of the fluid will augment rather than slow down obliteration, if it has the proper basis (fibrinous exudate). Transudates are resorbed without such a result. The lung will never reexpand completely because of fixation, but almost complete expansion may result if the fibrosis is not too dense. Dense fibrosis will sometimes encase the lung so that expansion is almost nil. There is no relation to the underlying lung lesion any more than that the infection usually emanates from a subpleural lesion. It is predominantly a pleural process.

The prognosis depends on the extent of underlying lung lesion, usually tuberculosis.

There is no treatment unless the lung lesion is due to an abscess, when resection and drainage may effect a cure, or to tuberculosis when a thoracoplasty may, and usually will, accomplish the result. In bilateral disease these operations may not be possible.

MENTAL AND PHYSICAL DEVELOPMENT IN PREMATURE INFANT

To the Editor:—A female infant weighing 4 pounds (1,800 Gm.) was delivered in September 1936 at about the eighth month of gestation. The delivery was normal and the child gained rapidly in weight: at 6 months 11 pounds (5 Kg.) and now at 17 months 21 pounds (9.5 Kg.). She has received cod liver oil and orange juice since 3 weeks of age and simlac almost from birth. At about 15 months of age she could neither sit straight by herself nor walk. She could stand erect by herself for a short time when supported, but when she was sitting her head drooped forward and her back arched. The first tooth appeared at 10 months and she now has eight. Her anterior fontanel is open and measures 1.5 cm. in diameter. X-ray examination of the wrist suggests healed rickets. She does not speak but seems to have normal intelligence. For the past six weeks she has had vitamin D and drisdol. She has been given ultraviolet radiation and a grain of desiccated thyroid daily for the past four weeks. She has improved slightly and sits somewhat more erect but not for any length of time. Suggestions as to diagnosis, prognosis and treatment will be appreciated.

M.D., Ohio.

ANSWER.—From the data presented it is obvious that the infant was premature. The fact that the child at 17 months does not sit up well is rather suggestive of cerebral injury, possibly a result of a cerebral hemorrhage, which occurs far more frequently in immature infants than in those born at full term. Development in prematurely born infants may be considerably delayed. Mental development, although somewhat slower than normal, is not usually so long delayed as is evidenced in this case. More detailed data, with employment of the Gesell Schedule as a basis, is required before any definite conclusion can be reached. The prognosis at the present time should be guarded and the child carefully watched as to the mental factor. Chances are fairly good that the intelligence will be impaired, although one is not justified in making this commitment to the family on the basis of the little evidence presented or without a longer period of observation. If she still has not progressed favorably after several months more, encephalography should be considered for the purpose of establishing the amount of cerebral tissue present. This, of course, is of value only from a prognostic point of view and not in any therapeutic sense.

The nutritional state of the infant sounds fairly good, although slightly below the expected level. The only treatment is to continue with all possible dietary aids. Whole milk in place of the artificial feeding would perhaps be beneficial.

Thyroid is good therapy, although it should not be given constantly. In addition, a full baby diet with plenty of vegetables, chopped meats, cottage cheese and fruits should be given. If three teaspoonfuls of one of the fortified cod liver oils now available are given daily, no further vitamin D is needed. Calcium in the form of calcium gluconate, a drachm (4 Gm.) in the day's milk supply, may help. In addition a few grains of iron and ammonium citrate mixed with a little yeast extract should be given to the infant as a further tonic.

ROENTGENOGRAPHY OF MASTOID

To the Editor:—Has any one ever done any research on the condition of the mastoid process, after definite involvement as indicated by x-ray examination, and on the x-ray appearance of this process after operation?

M.D., Iowa.

ANSWER.—A search of the literature of the last few years does not indicate any work in which there was a definite attempt to correlate what was found in the mastoid process after there was x-ray evidence of disease. The roentgenogram is a very valuable adjunct in the diagnosis of suppurative conditions of the mastoid process. Its use, however, unless coupled with experience and judgment, is apt to be fallacious. From the very beginning of an otitis, with its concomitant congestion of the mastoid process, there is x-ray evidence in the way of cloudiness in the mastoid area. Increased blurring and disappearance of the bony trabeculae are shown in the more advanced forms of the disease. With few exceptions the evidence given in the first week of an otitis is not of such a nature as to determine surgical intervention, and this is true also of mastoiditis which is more developed. The clinical observations determine the course and the treatment of the disease. The roentgenogram does tell how well pneumatized the mastoid process is, for example. Every otologist of experience has had occasion to compare what he has found at operation with what he saw on the x-ray film, and most men of experience are agreed that the x-ray evidence is often deceptive. Conditions found at operation may be frequently more extensive than indicated by the x-ray evidence, and the reverse also is true. X-ray examination may lead one to believe that there is extensive destruction and

the surgeon may find only a moderate involvement. It often happens, furthermore, that there will be a need for repeated x-ray examination after operation because the patient is not doing well. The large central operative cavity is usually clearly marked and, in addition, one can see those cells which the operative procedure cannot completely remove and also the cells of the petrosal part of the temporal bone, which are invaded by the surgeon in only a small percentage of cases.

The earlier stages of mastoid disease and the milder forms followed by recovery are seldom, if ever, noted because there is no need for surgical intervention. In cases in which surgical operation has been found necessary it is seldom that the pathologist gets to examine anything more than a number of bone fragments which are removed.

PAINFUL NOCTURNAL ERECTIONS NOT DUE TO TABES

To the Editor:—A man, aged 65, Jewish, had tabes about twenty-five years ago, after having contracted syphilis from twelve to fifteen years previously. He received the routine medication but was rather careless. Now he has almost all the principal symptoms of tabes but is able to attend to his business and would be more or less comfortable if not for one particular kind of attack, which occurs whenever he falls asleep. It consists in painful erection (devoid of any sexual feeling) always accompanied by a severe tingling sensation involving the whole body, reaching such a degree of painfulness that he can get rid of it only by forcing himself to wake up. The intensity of the sensation is in direct proportion to the soundness of his sleep and gradually disappears after he wakes up: first the erection and then, gradually, the tingling sensation. The attacks are getting more severe and the patient is developing a suicidal complex. What is the mechanism of this sensation, what is its connection with falling asleep, and what suggestions for therapy can be made?

M.D., Pennsylvania.

ANSWER.—The painful nocturnal erections of which this patient complains are almost certainly not associated with tabes dorsalis. If they rest on any organic basis they are probably due to a local lesion in the urinary tract. It is barely possible that they may be associated with overfilling of a neurologic bladder, but it is rather more likely that they are due to a hypertrophied prostate. Examination by a urologist is essential. If no organic lesion is found in the genito-urinary tract, the attacks are almost certainly on a psychic basis and, since the patient has become suicidal, he should be under the care of a psychiatrist.

PRESACRAL SYMPATHECTOMY AND PELVIC PAIN

To the Editor:—I have been hesitant about doing sympathectomies for severe dysmenorrhea, in fear of masking the pain of some future acute pelvic condition. Please give me the general consensus as to the safety of either lumbar or presacral sympathectomy during the reproductive period, especially from the standpoint of the effect on symptoms of possible future abdominal (pelvic) crises.

M.D., New York.

ANSWER.—Thus far there have been no reports of acute pelvic or abdominal crises following presacral sympathectomy. This operation will relieve pain which arises in most pelvic organs but by no means all of them. It will eliminate dysmenorrhea and pain due to carcinoma of the cervix, the body of the uterus and the bladder but not pain due to ovarian involvement. Most of the pain due to a ruptured ectopic pregnancy or twisted ovarian cyst is due to an irritation of the visceral and parietal peritoneum. The sensation of this pain is not transmitted through the sympathetic system but through the spinal cord. Hence, presacral sympathectomy may be performed for dysmenorrhea without any concern about the masking of pain in future pelvic and abdominal crises.

DEMONSTRATION OF BENZENE IN URINE

To the Editor:—Would you kindly outline the "urine sulfate test" as used in the detection of benzene intoxication?

M.D., Indiana.

ANSWER.—The test for benzene in the urine is the same as that for phenol. Urine that contains benzene or phenol becomes brown on standing. Benzene and phenol may also be demonstrated by distillation. The urine is strongly acidified with hydrochloric acid and distilled. To the first few cubic centimeters of the distillate is added 10 per cent ferric chloride solution drop by drop, and if phenol or benzene is present there will appear a deep amethyst blue color.

One tenth of the sulfates in the urine appear in combination with aromatic substances such as indole, phenol, benzene and skatole and are called ethereal sulfates. These are tested for by the Obermayer indican test as follows: To one third of a test tube of urine is added one third of a test tube of Ober-

mayer's reagent. To this mixture is added a few cubic centimeters of chloroform. The mixture is warmed slightly before the addition of the chloroform, and the tube is inverted several times to insure proper mixing. If indican is present in excess, the chloroform which settles to the bottom of the tube will assume an indigo blue. Conditions that lead to an excess amount of indican in the urine are diseases of the small intestine, slow flow of bile and absorption of exudates. In the absence of the aforementioned diseases, if there is an increase of indican in the urine, the urine should be distilled and benzene demonstrated in the distillate.

CATARACT AFTER TUBERCULOSIS AND GLAUCOMA

To the Editor:—A patient has a tuberculous condition of the right eye, which was diagnosed clinically and microscopically ten years ago. A few years later glaucoma set in and an iridectomy was performed to relieve tension. Injections directly in the eye were given with no avail. Later there were occasional exacerbations with adhesions developing. Now the lens of the eye is distinctly opaque (cataract formation) and vision is restricted to light perception. The tension of the eye is practically normal. There is considerable pain in the eye. The patient is eager to have the cataract removed. Would this be advisable, in view of the tuberculous history? Would the removal affect the good eye or would it be advisable to remove the entire eye?

DAVID GLASS, M.D., Louisville, Ky.

ANSWER:—If the eye is quite free from active inflammation as shown by freedom from fresh deposits on the cornea and some cells in the anterior chamber, it would probably be the best plan to remove the lens and at the same time to do an iridectomy. There would be some chance that this might stir up an attack of inflammation but it should be possible to control by foreign protein injections and atropine afterward. It is also quite likely that pathologic changes will be found in the fundus or opacities in the vitreous which will prevent a good visual result so that the patient should be prepared for this. There should be no more danger to the good eye than after any operation for cataract, although one should be sure that there is no inflammation in that eye which might be present in spite of the normal vision.

DYEING HAIR

To the Editor:—A patient engaged in the daily practice of dyeing hair has vitiligo and scattered tufts of white hair on the scalp. These tufts fail to take the dye by the same methods used on others. Is this experience unusual? Is there any particular kind of dye which can be tried in such a case? Jackson and McMurtry (*Diseases of the Hair*, Philadelphia, Lea & Febiger, 1912, p. 359) say that the use of hair dye will conceal this condition. I have not found this point discussed in other textbooks consulted.

M.D., Rhode Island.

ANSWER:—The idea has long prevailed that hair has individuality. One person's hair takes dye much more readily than does another's, although the two may appear of the same texture. One person's hair may color well with vegetable dye and poorly with metallic dye, while hair apparently of the same texture and oiliness on the scalp of another person may give just the opposite reaction, dyeing well with metallic but poorly with vegetable dyes. Even hair in different places on the same scalp may show a difference in respect to dyeing. Gray hair is particularly hard to dye.

Galewsky writes (*Handb. d. Haut u. Geschlechtskr.* 13:165, 1932) that the beard and scalp hair of the same man will differ in respect to dyeing. Soft fine hair is harder to dye than coarse stiff hair. According to the hardness of the cuticle of the hair, the color will penetrate better and be more lasting. Later growing hair, which has more fat and less keratin, often gives a different color and the same is true of the parts next the scalp as the hair grows out. Variations in sulfur content, the effects of nervous disease, attacks of migraine and circulatory disturbances are thought to affect the ease with which hair can be dyed.

Washing with soap and water is a good preparation for dyeing, and in some instances the use of a weak alkali or of hydrogen peroxide may be a necessary preliminary to the application of the color. Strong defatting agents, ether, benzene or carbon tetrachloride are said to dry the hair too much and make dyeing more difficult.

For the management of the case in question it seems advisable to try different dyes until one is found that will affect the gray hair. Sabouraud's suggestion, that all persons who wish to have the hair dyed should first have the dye tried on a small spot to determine how well the dye takes and whether the individual is sensitive to it, is a good one. When the most suitable dye has been found, the white patches should be dyed first until they approach in color the rest of the hair. A patch which includes both light and dark hair is then dyed and if the result is satisfactory the whole may be dyed. No sugges-

tion as to the particular dye can be made. It should be understood that all dyes are potentially dangerous; but, if the patient insists that the hair be dyed, the dye most familiar to the operator should be preferred if there are several that seem to give good results.

MORTALITY IN APPENDICITIS

To the Editor:—Where can I get some definite information on the mortality rates in untreated cases of acute appendicitis? Have any such figures been compiled for the period before the advent of appendectomy? Of course, I know that the operative mortality for chronic appendicitis is practically nil and that the mortality for gangrenous appendicitis with peritonitis is about 20 to 25 per cent, depending on the different operators. What I am especially interested in is the mortality figures for appendicitis when no surgical treatment was received at all.

BENJAMIN A. FURMAN, M.D., Newark, N. J.

ANSWER:—Any statistics compiled before the surgical treatment of acute appendicitis would be of no value, because when this condition gradually came to be recognized clinically the patients were frequently operated on. At first only the late cases with peritonitis were diagnosed, many of the patients being moribund. Earlier clinical diagnosis and operation soon led to a reduction of the mortality. It is not infrequent at the present time to see a patient develop peritonitis from a ruptured appendix while under the observation of a physician inexperienced in surgical diagnosis.

Mortality following operation for chronic appendicitis may occur from the common or even unusual postoperative complications, but it increases more directly with the inexperience of the surgeon. In recent years it has been considered to be good practice in many cases of acute appendicitis with perforation and well localized peritonitis to treat without operation. Several months later the appendix should be removed. Other surgeons of wide experience operate in all cases as soon as the diagnosis has been made, with equally good results.

In cases of general peritonitis, Miller and Turner (*Illinois M. J.* 72:222 [Sept.] 1937) have reported a series treated with and others without operation but are undecided as to the best procedure.

No statistics are available for nonoperative treatment of acute appendicitis, because today in all scientific institutions these patients are operated on before perforation occurs, unless some contraindication exists.

DRIPPING FROM RECTUM

To the Editor:—A farmer, aged 65, has had chronic diarrhea for the last eight months, averaging from six to eight movements a day. He has had also a persistent dripping from the rectum; brownish colored fluid has reached his shoes when he is working. There are no other symptoms. With the use of a bismuth compound the movements have been decreased to one normally formed movement a day; however, the rectal dripping persists throughout the day unabated. The history and physical examination are essentially negative except for obesity and hypotension: 109/75. Please suggest a mode of treatment to stop this dripping.

M.D., Pennsylvania.

ANSWER:—Many serious rectal conditions are associated with "dripping" of the type described. This condition has been noted with various types of proctitis, ulcerative colitis, and even anal neoplastic disease. Sometimes kraurosis ani is accompanied by this condition. Various local applications and injection treatments for kraurosis ani have been used. However, in the inquiry the results of the digital examination or of cultures and examinations of the stools and rectal discharges are not mentioned. Moreover, the appearance of the rectal lining as seen through the proctoscope or the results of roentgenologic examination of the intestine are not given. To suggest treatment without this information would be unwise.

VARIATIONS IN SYSTOLIC BLOOD PRESSURE

To the Editor:—Why is it that, when one takes several successive blood pressure readings without removing the arm band, the first systolic reading is almost always higher than the succeeding ones? What should be taken as the true systolic pressure?

LUTHER W. HIGH, M.D., Millersburg, Ohio.

ANSWER:—There are two reasons for the difference in readings. Even apparently stolid and phlegmatic persons frequently feel some apprehension as the blood pressure is taken and hence the first reading is found at a higher level. Also the muscles of the arm are held tense and constricted, especially if the arm is not in a comfortable position, causing a higher reading. As the patient gains assurance, the arm is relaxed and the muscles do not respond to the increased pressure of the cuff, with involuntary contraction, as at first. Care taken to have the

arm in a comfortable and relaxed position will help obviate a high reading due to muscle tension in some cases.

It is a good plan to record the initial reading and also the last reading after the patient is reassured and relaxed. It gives some idea of how much the patient responds to nervous stimuli.

DIPLOPIA AND STRABISMUS FOLLOWING SPINAL TAP IN SYPHILITIC PATIENT

To the Editor:—A white woman, aged 26, was given a twelve months course of neosarsphenamine seven years ago at the time her marriage. When I first saw her, nine months ago, she was in the sixth month of her first pregnancy. She was then given weekly injections of a bismuth compound and neosarsphenamine. The pregnancy was uneventful except for a positive cord Wassermann and blood Wassermann test on the baby. The mother's blood Wassermann reaction has remained positive in spite of continued treatment. Three weeks ago I did a spinal tap; the fluid was entirely negative. For a week afterward the patient suffered severely from nausea, vomiting, headache and dizziness on arising. Then she noted diplopia of the right eye and had to cover the eye in order to see clearly. Shortly after this I noted a strabismus, which has persisted together with the diplopia. The other symptoms have cleared up. Examination of the eyes reveals nothing further. Could you explain the mechanism underlying these phenomena? What treatment, if any, should be given? The blood Wassermann reaction of the patient was positive (4 plus) when I first saw her.

M.D., New York.

ANSWER:—As the affected eye muscle is not named, it can only be inferred that either the third or the sixth cranial nerve is involved. In spite of the negative spinal fluid tests there is probably a syphilitic lesion at the base of the brain involving one of these nerves. The upheaval caused by the loss of the fluid cushion has brought about a change in position of one of these nerves, resulting in a partial paralysis. The latter will probably soon subside and may have been a blessing in disguise, as it shows that treatment for neurosyphilis is indicated. In view of the long duration of the syphilis in this case a course of tryparsamide is indicated. It is recommended that only 1 Gm. intravenously be given for the first dose, 2 Gm. four days later, and if the optic nerves show no signs of being affected, 3 Gm. may then be given every week for six doses. After a rest period of a month it will be well to repeat the course even if the strabismus has cleared up. Subsequent treatment will have to be planned according to the condition of the patient.

PHYTOSTEROLS AND PHENYLMETHYL BARBITURIC ACID

To the Editor:—What common plants and animal tissues used for food by human beings contain phytosterols? If phenylmethylmalonylurea is marketed in this country, what is the proprietary name or names?

I. D. CLARK JR., M.D., Fargo, N. D.

ANSWER:—Phytosterols, a group of sterols similar chemically to cholesterol, occur only in plants, where they are found especially in the oils of seeds. Sitosterol is the principal plant sterol of wheat and barley germs, cottonseed oil and laurel oil. Stigmasterol is present in the calabar bean, beet oil, coconut oil, theobroma oil and corn oil, which contains dihydrositosterol also. Phytosterols are not absorbed in significant amounts through the intestinal walls of ordinary laboratory animals and are believed to have no significance in the sterol metabolism of man.

According to available information, phenylmethyl barbituric acid (phenylmethylmalonylurea) is not marketed in this country at the present time.

VISUAL EFFICIENCY AND VISUAL ACUITY

To the Editor:—Why isn't visual acuity equal to visual efficiency? If this is fully answered in any available place, please tell me where. The test chart, American Medical Association rating, has visual acuity and visual efficiency on it. At 1.0, or 20/20 visual acuity, the visual efficiency is 100 per cent. That is the only place where they are equal. At 0.10, or 20/200 visual acuity, the visual efficiency is 20 per cent, just double.

M.D., New York.

ANSWER:—Visual acuity, as expressed by reading of the Snellen charts, describes only the results of examination under the conditions of the test. 20/40, for instance, means only that letters are read at 20 feet which should be read at 40 feet. The committee on estimation of industrial loss of vision in 1925 estimated the loss of efficiency represented by these figures and arrived at the figures given in its report. Most ophthalmologists put in their records the fraction of the Snellen chart, 20/20, 20/40, and so on, and give the industrial efficiency only in reports involving visual loss in industrial cases. These figures describe only loss of central vision; losses of motility or visual field are estimated separately and totaled as described in the report.

ANAL FISSURES IN INFANT

To the Editor:—A baby 6½ months old has fissures circumanally that are entirely outside the mucocutaneous junction. They have appeared and disappeared since shortly after birth. The child has been on a diet of evaporated unsweetened milk and a mixture of maltose and dextrin. It weighs approximately 18 pounds (8 Kg.). Treatment has consisted of keeping the bowel movements soft by regulation of diet and care to keep the child dry at all times. An anesthetic ointment has been used also without much apparent benefit.

M.D., Indiana.

ANSWER:—The treatment for the anal fissures should be satisfactory. While it is stated that care is taken to keep the child dry at all times it is not always possible to do this. It might be advisable to add from one to two heaping teaspoonfuls of boric acid powder to the water in which the diapers are boiled. If the fissures persist they may be treated by touching them with a 5 per cent silver nitrate solution occasionally. This will usually aid in their healing.

AMMONIUM CHLORIDE FOR LONG PERIOD

To the Editor:—Is there any harm that could result from the continuous taking of ammonium chloride (20 grains, or 1.3 Gm., a day) over a long period? The patient is in bed with tuberculosis and has, in addition, a prostatic hypertrophy. The ammonium chloride is used not primarily as an expectorant but to keep the urine acidified. Mandelic acid with the ammonium chloride has been taken from time to time. None, however, is taken now. Please advise.

M.D., Maine.

ANSWER:—Probably no harm would result from taking 1.3 Gm. of ammonium chloride over a long period, but the question naturally arises What is the use? The object in taking the drug is to acidify the urine sufficiently to be bacteriostatic. For this purpose 1.3 Gm. would be quite insufficient in most cases. Unless the pH of the urine is 5.5 or lower, it would have little or no effect on urinary infection. If this complication is present, sulfanilamide might be tried in a daily total dosage of 2.6 Gm. over a period of a week or ten days. In the presence of residual urine, however, it may be impossible to disinfect the urine and keep it free from bacteria.

EAR AND TEMPOROMANDIBULAR JOINT SYNDROME

To the Editor:—I am interested in the work which Dr. James B. Costen, St. Louis, and others have been doing on the temporomandibular joint syndrome complex. Please let me know your opinion on these observations and whether his conclusions are accepted by a large percentage of physicians. I am interested in the subject from the otologic standpoint.

M.D., Nebraska.

ANSWER:—The work that Dr. James B. Costen of St. Louis has done on the temporomandibular joint syndrome complex has been accepted by many physicians and there is good reason to believe that pains in the region of the ear, and even as far away as the larynx as well, may be due to an arthritis in the joint. On occasion deafness of a eustachian tube type may occur, although some have stated that this condition is a rarity in their experience. Deafness of a more serious and progressive nature is more likely to be due to otosclerosis or auditory nerve degeneration and not to the condition described by Dr. Costen.

There is evidence that some members of the profession have become overenthusiastic and are recommending tedious, time consuming and expensive dental manipulation for the relief of these incurable types of deafness. Tubal catarrh can be treated and cured by inflation, and the associated Costen syndrome can be relieved by proper dental care. Dr. Costen's work should receive respectful attention, but overenthusiasm is to be deprecated and avoided.

STERILIZING SYRINGES WITH ALCOHOL

To the Editor:—I should like information relative to the sterilization of hypodermic syringes and needles by immersion in 70 per cent alcohol. If a syringe should be kept in such a solution in a special container in my kit, would the small amount of alcohol remaining in the syringe interfere in any way with the action of the usual vaccines given (catarrhal, Sauer's, Schick test)?

M.D., Texas.

ANSWER:—The accepted method for preparing the needle and syringe for subcutaneous, intradermal or intramuscular injections is by boiling in distilled water or by autoclave. Most of the usual vaccines and the specific toxins employed in the Schick and Dick tests contain globulins or globulin fractions that might be precipitated or interfered with by alcohol in the syringe. In using certain undenatured bacterial antigens it is specifically recommended that the needle and syringe be sterilized by boiling or hot air, as alcohol or other antiseptics carried into the vial will denature the antigen. Finally, sterilization produced by proper boiling or hot air is probably much superior to sterilization obtainable by using 70 per cent alcohol.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

ALASKA: Juneau, Sept. 6. Sec., Dr. W. W. Council, Box 561, Juneau.
ARKANSAS: Little Rock, Nov. 3-4. Sec., State Medical Board of the Arkansas Medical Society, Dr. L. J. Kosminsky, Texarkana.

CALIFORNIA: Reciprocity. Los Angeles, July 11, San Francisco, Sept. 14, and Los Angeles, Nov. 16. Written examinations. Los Angeles, July 11-14, and Sacramento, Oct. 17-20. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

CONNECTICUT: Medical (Regular). Hartford, July 12-13. Endorsement. Hartford, July 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. Medical (Homeopathic). Derby, July 12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 12-14. Reciprocity. Dover, July 19. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: Washington, July 11-12. Asst. Sec., Commission on Licensure, Mr. Paul Foley, 203 District Bldg., Washington.

HAWAII: Honolulu, July 11-14. Sec., Dr. James A. Morgan, 48 Alexander Young Bldg., Honolulu.

IDAHOO: Boise, Oct. 4-5. Commissioner of Law Enforcement, Hon. J. L. Balderston, 205 State House, Boise.

ILLINOIS: Chicago, Oct. 18-20. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield.

IOWA: Basic Science. Des Moines, July 12. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines. Massachusetts: Boston, July 12-14. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MONTANA: Helena, Oct. 4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEVADA: Reciprocity. Carson City, Aug. 1. Applications must be completed and on file by July 17. Sec., Dr. John E. Worden, Capitol Bldg., Carson City.

NEW HAMPSHIRE: Concord, Sept. 15-16. Sec., Board of Registration in Medicine, Dr. Fred E. Clow, State House, Concord.

NEW MEXICO: Santa Fe, Oct. 10-11. Sec., Dr. Le Grand Ward, 135 Palace Ave., Santa Fe.

NEW YORK: Albany, Buffalo, New York, and Syracuse, Sept. 19-22. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, 315 Education Bldg., Albany.

OKLAHOMA: Basic Science. Oklahoma City, Dec. 7. Sec. of State, Hon. Frank C. Carter, State Capitol Bldg., Oklahoma City.

OREGON: Basic Science. Corvallis, July 16 and Portland, Nov. 19. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PUERTO RICO: Santurce, Sept. 6-10. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

SOUTH DAKOTA: Rapid City, July 19-20. Director of Medical Licensure, Dr. B. A. Dyar, State Board of Health, Pierre.

WASHINGTON: Basic Science. Seattle, July 14-15. Medical. Seattle, July 18-20. Dir., Department of Licenses, Mr. Harry C. Huse, Olympia.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, July 2, page 87.

Kentucky Reciprocity and Endorsement Report

Dr. A. T. McCormack, secretary, State Board of Health of Kentucky, reports nineteen physicians licensed by reciprocity and two physicians licensed by endorsement from Jan. 13 through May 3, 1938. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Northwestern University Medical School	(1936)		Ohio
Rush Medical College	(1937)		Wisconsin
University of Illinois College of Medicine	(1931)		Illinois
Indiana University School of Medicine	(1930)		Indiana
University of Louisville School of Medicine	(1929)		S. Dakota
Univ. of Michigan Dept. of Medicine and Surgery	(1898)		Ohio
Columbia Univ. College of Ph	(1921)		New York
University of Cincinnati College			Ohio
Western Reserve University S			Ohio
Univ. of Tennessee College of			Tennessee
University of Tennessee Medical Department	(1900)		W. Virginia
Medical College of Virginia	(1925)		Virginia
University of Virginia Department of Medicine	(1931)		Maryland
University of Toronto Faculty of Medicine	(1922)		Michigan
School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Harvard University Medical School	(1932)		N. B. M. Ex.
University of Pennsylvania School of Medicine	(1933)		N. B. M. Ex.

Tennessee March Examination

Dr. H. W. Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held at Memphis, March 23-24, 1938. The examination covered ten subjects and included 100 questions. An average of 75 per cent was required to pass. Twenty-eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Arkansas School of Medicine	(1937)		85.7
Emory University School of Medicine	(1937)		85.7

Tulane University of Louisiana School of Medicine	(1937)	85.5
University of Tennessee College of Medicine	(1938)	81.2,
82.7, 83.2, 83.7, 83.8, 84.2, 84.3, 84.3, 84.4, 84.4,		
84.6, 84.7, 84.7, 84.9, 85, 85.2, 85.3, 85.4, 85.6, 85.9,		
86.1, 86.3, 87.9, 88.7		
Universität Heidelberg Medizinische Fakultät	(1933)	82.5

Three physicians were licensed by endorsement from February 25 through May 2. The following schools were represented:

School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
Atlanta School of Medicine	(1908)		Alabama
Tulane University of Louisiana School of Medicine	(1936)		Louisiana
Washington University School of Medicine	(1936)		Missouri

New Mexico April Report

Dr. Le Grand Ward, secretary, New Mexico Board of Medical Examiners, reports the written examination held at Santa Fe, April 11-12, 1938. The examination covered 12 subjects and included 90 questions. An average of 70 per cent was required to pass. One candidate was examined and passed. Thirteen physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Chicago Medical School	(1938)		85.7
School	LICENSED BY ENDORSEMENT	Year Endorsement Grad.	of
College of Medical Evangelists	(1919), (1936)		California
College of Physicians and Surgeons, Los Angeles	(1910)		California
University of Colorado School of Medicine	(1936)		Colorado
Bennett Medical College, Chicago	(1916)		Illinois
Northwestern University Medical School	(1937)		Washington
Indiana University School of Medicine	(1936)		Indiana
Harvard University Medical School	(1934)		N. B. M. Ex.

Book Notices

The Biology of Pneumococcus: The Bacteriological, Biochemical, and Immunological Characters and Activities of *Diplococcus Pneumoniae*. By Benjamin White, Ph.D. With the collaboration of Elliott Stirling Robinson, M.D., Ph.D., and Laverne Almon Barnes, Ph.D. Cloth. Price, \$4.50. Pp. 799, with illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1938.

The Commonwealth Fund through (the late) Dr. White and his collaborators has contributed a service to medical science through its publication of this volume, which would be noteworthy even if only because it has set a precedent. As the author points out in the foreword, the motive in writing the book was to "take stock." In this instance the stock taking has been done by men who, while interested in the pneumococcus and pneumonia, have been far enough removed from the work to be unprejudiced. The title aptly describes the contents of the book, although biology, as here described, borders on romance at times. The authors have traced the evolution of our knowledge of the pneumococcus from the first observations by Pasteur and Sternberg to the present day methods of combating pneumococcal infections. It is primarily attractive to the bacteriologist and laboratory scientist, unfortunately less so to the practicing physician. Despite the breadth of the subject the book is well proportioned, including a prodigious bibliography of more than 1,500 references. The style of writing should be a model for more writers of scientific articles. It is unfortunate that the authors did not see fit in writing a book which probably will be a source book for many years to discontinue the use of "Group IV," a term which has always been a misnomer and which has already caused too much confusion. It is again refreshing to find an author who can present controversial matters, fix the issue and arrive at an unequivocal decision without appearing to be arbitrary. The final chapter, on unsolved problems, is a fitting close to a book which starts out to determine "how far the store of the bullion in the cellar is really the solid gold of truth."

Megacolon und Megacystis: Entstehung, Erkennung und Behandlung. Von Dr. Hans Wolfgang Passler, jetzt Chirurg. Univ.-Klinik Leipzig. Mit einem Geleitwort von Prof. Dr. Wilhelm Rieder, Direktor der Chirurg. Univ.-Klinik, Leipzig. Paper. Price, 15.60 marks. Pp. 172, with 67 illustrations. Leipzig: Johann Ambrosius Barth, 1938.

This is an attractive volume on megacolon and on the large bladder, which in rare cases is found associated with megacolon. Passler has seen the association in three cases and has found reports of some eighteen cases in the literature. The large bladder is likely to be seen only with those cases in which the whole colon, including the rectum, is involved. Passler first reviews the important points in the anatomy, embryology and innervation of the colon and the bladder. He then discusses Hirschsprung's disease in its various aspects. The book is well written and well illustrated. There is much on the surgical treatment of the disease not only by Passler but by many surgeons who have worked in this field. Table 4 shows that of 117 patients with apparently idiopathic megacolon operated on by neurosurgeons thirty-eight were cured, sixty-four were improved and twelve were not helped. Three died sometime after the operation. Passler summarizes briefly thirty different theories as to the cause of the disease. His

impression is that all the clinical and experimental observations point to something wrong with the sympathetic nervous system. Passler has not given sufficient prominence to the studies which have shown that Auerbach's plexus is generally absent or much thinned out in that distal part of the bowel which does not dilate. The simplest explanation for megacolon would be an absence of the local nervous system because biologists have shown that when smooth muscle is cut away from its immediate nerve supply it contracts down into a hard knot and stays that way. Actually there is no question that in some of these cases the myenteric plexus is absent. However, the fact that section of the pelvic sympathetic nerves will sometimes bring relief in cases of Hirschsprung's disease makes it appear that there is disease also in the extrinsic nerves of the bowel. Passler states, though, that men who have looked for disease in the ganglions removed at operation haven't seen much change from normal.

Passler divides cases of megacolon into three groups. In one the colon is distended only to the right of the splenic flexure. In this case, perhaps, the defect is in the superior mesenteric plexus of nerves. In the second group the whole colon except the rectum is involved, and Passler's impression is that the inferior mesenteric plexus is diseased. In the third group the whole colon, including the rectum, is enlarged, and here the hypogastric plexus may be diseased. Passler believes that treatment in these three types of cases should be different and that if nerves are cut the extent of the operation should depend on the extent of the disease. He believes that this division is of importance because the cutting of nerves is of value in only certain of the groups and not in others.

The book should be helpful to all those men who are interested in this puzzling disease. They doubtless will want to go back to the original articles in order to study them carefully. Unless a man with much detailed knowledge of the subject notes that one experimenter studied dogs under ether, another studied patients under local anesthesia and another studied cats with an abdominal window or with the roentgenologic technic, he will not be able to reconcile the many differences of opinion which he will find expressed in the many articles on the innervation of the lower part of the colon. The bibliography of nearly 400 titles will doubtless be of much value for all men working in this field.

Text-Book of Ophthalmology. By Sir W. Stewart Duke-Elder, M.A., D.Sc., Ph.D., Surgeon Oculist to H. M. The King. Vol. II: Clinical Methods of Examination, Congenital and Developmental Anomalies, General Pathological and Therapeutic Considerations, Diseases of the Outer Eye. Cloth. Price, \$15. Pp. 2,094, with 742 illustrations. St. Louis: C. V. Mosby Company, 1938.

The first of this four volume textbook was reviewed in this column June 24, 1933, with great enthusiasm. Its reception by the ophthalmologic profession was really in the nature of an ovation and the only critical works were the expressed fears that the task of producing the remaining volumes might prove too great or that the lofty standards set in the first volume were too high to be maintained. But the appearance of the second volume has set all those fears at rest. The interval of production is a bit longer than desirable, but it was worth waiting for. The publishers are to be congratulated on the excellence of their production not only from the mechanical standpoint of book-making but even more because of the fine illustrations, both black and white as well as colored. The illustrations really illustrate, so that even an undergraduate medical student can grasp the point in question. This volume deals with the clinical methods of examination, congenital and developmental anomalies, and general pathologic and therapeutic considerations of diseases of the eye and specifically of the conjunctiva, cornea and sclera. The material is presented in such a thorough and systematic manner that one marvels at what type man it is who can write so ably. His English is not stilted but flows freely and conversationally and his word pictures of ocular conditions are so descriptive that illustrations are almost unnecessary. Following each entity is a short but comprehensive bibliography that furnishes the key to all that has been written on the topic. Each important chapter is opened by a short outline of the life and work of the ophthalmologist whose name is most intimately connected with the subsequent pages. Von Graefe is naturally

given the place of honor at the beginning of the volume. This new touch in ophthalmic textbooks should prove most stimulating to the younger men who have not yet acquired the leisure to study the history of ophthalmology. It is obviously impossible to deal with individual phases of the work in a short review, for all that the reader wishes to know is what the book is about and whether in the opinion of the reviewer the book is worth while. To the latter, most emphatically, yes. It is the most complete thing that has been produced in English, it contains the last word in modern ophthalmology and it renders entirely unnecessary the long drawn out and never ending handbuchs of the Teutons. Anglo-Saxon ophthalmology owes a real debt of gratitude to Duke-Elder not only for his brilliant research work but even more for his textbook.

Tumeurs Intracranienne: Etude analytique de 2000 tumeurs vérifiées et de leur mortalité opératoire. Par Harvey Cushing, professeur de neurologie à la Faculté de médecine de Yale, New Haven. Edition revue et augmentée par l'auteur et comprenant deux études sur les résultats éloignés du traitement opératoire des tumeurs intracrâniennes. Par W. P. Van Wagenen et Hugh Cairns. Traduction française de Jean Rossier. Paper. Price, 80 francs. Pp. 194, with 111 illustrations. Paris: Masson & Cie, 1937.

This is a French edition of "Intracranial Tumours," published by Charles C. Thomas, Springfield, Ill., in 1932. The book passed through a German edition in 1935, to which an abstract of a study of 149 cases of brain tumor eight years after operation by Dr. W. P. Van Wagenen of Rochester, N. Y., was appended. In the present edition a second study by Mr. Hugh Cairns of London of 157 other cases from eight to nine years after operation has been added. These two studies attempting to assess not only the actual postoperative survival period in months but the economic and social status of the patients during this period as well are valuable additions to this work. The original monograph by Dr. Cushing has been little changed. This monumental record of the surgical achievements of one man is thoroughly familiar to all interested American and English neurologists and neurosurgeons. It must be gratifying to all American members of the profession to have it made available to our German and French speaking colleagues. This monograph consists essentially of the surgical-mortality statistics of the various types of tumors of the brain and with the two appendixes cited, which have been added to this edition, a statistical study of the ultimate prognosis in a more limited group of cases as well. That this record represents the final achievement of neurosurgery the author would be the first to deny. But it does represent a definite goal which all neurosurgeons will seek to achieve and if possible surpass. The book will prove useful not only to surgeons of the brain but to all members of the profession confronted with the puzzling problems of tumors of the brain. This edition is well printed; the illustrations, apparently prepared from Mr. Thomas's original plates, are well reproduced.

Sickness and Insurance: A Study of the Sickness Problem and Health Insurance. By Harry Alvin Mills, Professor of Economics, The University of Chicago. Cloth. Price, \$2. Pp. 166. Chicago, Illinois: University of Chicago Press, 1937.

In general, this discussion of health insurance is more impartial and gives greater consideration to the attitude of the medical profession than the majority of the writings by the advocates of health insurance. There is one important qualification of this judgment. The reports of the Committee on the Costs of Medical Care are accepted unreservedly, with the specific statement that "there has been general acceptance and little but praise of the fact-finding done." On the contrary, it is just the technic used in the "fact-finding" and the accuracy of the alleged facts concerning the basic features of amount and distribution of illness and medical care that have been most sharply challenged. The quotation from the Committee on the Costs of Medical Care (page 152) that "thousands of persons are sick and dying in this country because the knowledge and facilities that we have are inadequately applied" is a good example of the misleading statements of the committee. No effort is made by either the committee or the author to show that fewer persons "are sick and dying" in any country where insurance has been applied. The program offered by the author,

however, is much less sweeping and impracticable than is usually proposed. "It includes (1) an extended and improved public health service; (2) an amended Social Security Act so as to provide cash benefits for wage-earners when disabled by sickness as well as when unemployed because of lack of work; (3) appropriate tax-supported medical care for special groups; and (4) organized medical care of persons in the lower-income groups when involved in high-cost illness, with the costs met by compulsory insurance contributions and tax revenues."

Third Symposium on Silicosis. An Official Transcript of the Third Silicosis Symposium Held in Connection with the Trudeau School of Tuberculosis at Saranac Lake, N. Y., June 21 to 25, 1937. Edited by B. E. Kuechle, Vice President and Claims Manager, Employers Mutual Liability Insurance Co., Wausau, Wis. Paper. Price, \$3. Pp. 266, with illustrations. Wausau, Wis., 1937.

This is the official transcript of the third symposium on silicosis, held in connection with the Trudeau School of Tuberculosis at Saranac Lake, N. Y., June 21 to 25, 1937. The symposium consisted of thirteen lectures, which in their entirety deal with all aspects of silicosis, from etiology to the administrative problems involved. Following each paper is a discussion in which the author frequently expresses an opinion not noted in the paper. For example, Dr. Sayers was asked whether disability from silicosis could be measured physiologically before x-ray diagnosis had been made, to which he replied in the negative. The final diagnosis depends on the degree of disability, on the x-ray appearance and on other physical observations. The progressive tendency of the disease after removal from dust exposure was brought to the attention of all by Dr. Sayers, who referred to the works of Bohme and Russell. In this country most workers dealing with the silicosis problem accept the opinion that uncomplicated silicosis is not an incapacitating disease but is the menace that it is because it specifically predisposes to tuberculosis. The pathology, pathologic physiology, roentgenology, clinical picture and control methods from medical, engineering and legal aspects are ably presented and discussed. The book represents much of the latest and best thought on silicosis. Worthy of favorable comment is the fact that this transcript is indexed. The first two transcripts (1933 and 1935) were not indexed.

The Compleat Pediatrician: Practical, Diagnostic, Therapeutic and Preventive Pediatrics for the Use of Medical Students, Internes, General Practitioners, and Pediatricians. By Wilburt C. Davison, M.A., D.Sc., M.D., Professor of Pediatrics, Duke University School of Medicine, Durham, N. C. (Adaptation of the Title Page of *The Compleat Angler* by Izaak Walton, 1653.) Second edition. Cloth. Price, \$3.75. Pp. 276. Durham, N. C.: Duke University Press, 1938.

The second edition of this cross index pediatricus has profited by the experimental presentation of the first. The first edition suffered in usefulness to the student and the general practitioner because its inclusive material was offered in a too brief and staccato manner. The present form of presentation really gives a portrait of the subjects discussed. The style consists of a running description, and the eye is not so much distracted by the large cross reference numbers. The page is divided into two columns, further adding to readability. Conforming to the original, this edition numbers the subjects but not the pages. The number of sections has been reduced by combining the material in groups. For instance, the 329 pediatric diseases have been gathered into 133 groups, the 164 signs and symptoms into ten paragraphs and the 213 laboratory tests and therapeutic technics into thirty-three divisions. New sections on growth, development, nutrition and infant mortality have been added. The entire subject matter has been divided into thirteen instead of the original seven chapters, conforming more closely to the conventional textbook. At the same time an enormous amount of detailed information has been compressed into the 250 sections, replacing the original 1,957. As in the first edition, the last numbered section does not indicate the number of sections in the book. For instance, the chapter on laboratory procedures ends with section 207, while the next chapter begins with 213. In fact, the curious but consistent omission of six between the numbers of sections ending one chapter and beginning the next puckers the brow and kindles an interrogative flash of the eye. Why? By this omission there are really 178 sections in the

book by reason of twelve hexajumps instead of the printed 250. The mathematical nature of this review so far merely reflects the mathematical framework on which this volume pins its text. This statement is at once an explanation and an apology, because it is impossible to do justice to the mass of specific and authoritative information compressed between the flexible covers of this book. Frequent editions assembling and assaying the mass of pediatric literature accomplished so successfully and effectively should be welcomed because no doctor can do justice to himself in the field of pediatrics without this notebook-library of pediatrics. Although the composition of the encyclopedia is still unique, the reader will be gratified to find this quality somewhat sacrificed for greater clarity and availability. Before it was a short cut for the professor. Now even a student will find it useful. Abstaining from the excesses of originality in which he indulged his first edition, the author has sobered his performance temperately.

Les embolies artérielles des membres. Par H. Haimovici. Préface de MM. R. Leriche et J. Fiolle. Paper. Price, 55 francs. Pp. 336, with 25 illustrations. Paris: Masson & Cie, 1937.

This monograph should be translated into English. It is such a splendid piece of work, complete in every detail—with one possible exception—that it ought to be available to every one. Starting out with a brief preface by Leriche and his colleague Fiolle, wherein they make the point that this is the first analytic research devoted to arterial embolism of the limbs—to which the author devoted two years—the book first gives a short historical review, followed by a study in etiology; three fourths of the cases followed cardiac disease. Next comes a chapter devoted to symptomatology, following which there is an extensive clinical study wherein many illustrative cases are cited. In the chapter on diagnosis the author calls attention to the fact, which others have noted, that arterial spasm may, under certain circumstances, simulate an embolism. In the section devoted to pathology, numerous satisfactory photomicrographs are found. The most interesting section, devoted to treatment, is divided into two parts, the first being nonsurgical, in which various drugs such as acetylcholine are used, and the second being surgical, with chief emphasis on surgery. Embolectomy, arteriectomy, sympathectomy, anastomosis and ligations and, finally, amputation are considered in the order named. The time element is most important in considering an embolectomy. If more than from ten to twelve hours has elapsed from the time the embolus has occurred, operation is contraindicated. In certain later cases arteriectomy may be helpful. The only real criticism to be made is that Dr. Haimovici fails even to mention the passive vascular exercise method of treatment. This is unfortunate, because it may well be that passive vascular exercise will eventually supplant all other methods of treating embolic accidents to peripheral arteries. There is an extensive bibliography.

Report on the Assistance of Indigent Patients Suffering with Epilepsy. The Minnie Frances Klemm Memorial Fund. The Department of Nervous and Mental Diseases, Northwestern University Medical School, Chicago, Illinois. Cloth. Pp. 567, with 9 illustrations. Ann Arbor, Mich.: Edwards Brothers, Inc., 1936.

This work is planned to indicate work done and the opportunity for great discoveries if more funds are granted. The book opens with facsimiles of letters indicating that the chairman of the department presents to a medical "liaison officer" a report on the "assistance of indigent patients suffering with epilepsy." The liaison officer then writes that he has the honor to transmit the report to the dean of the medical school, and finally the dean forwards the report to the bank from which the funds came, including a request that the description of patients be kept strictly confidential. Later in the volume are sixty-five pages of clinical descriptions. On page 65 is the statement "Certainly we feel that nowhere else in America is there opportunity for study of epilepsy comparable to this." There are photographs of the medical school and of various bits of apparatus, clinic benches and hospital beds. It is also stated that research in epilepsy such as reported could be done only by a great university and certainly not by an independent hospital or research institute. This study concerned three groups of patients totaling ninety-six individuals. The usual

classification of the epilepsies and etiologic concepts is followed. It is said that tubular vision is common in epileptics, which is surprising. All the body fluids were examined with the usual negative results. Surgical treatment is used when indicated to remove scars. A ketogenic diet, bromides and phenobarbital are successfully prescribed and dehydration is discarded—all in accordance with general experience. Auras are ascribed to excitation of the brain stem in opposition to the usual view that they arise from the cortex, but the evidence is not conclusive. As a scientific treatise the value of this report lies in reiteration of what is already well known.

Los ruidos cardíacos en condiciones normales y patológicas. Por Oscar Orías, doctor en medicina, director del Instituto de fisiología y profesor de fisiología de la Facultad de ciencias médicas de Córdoba (Argentina), y Eduardo Braun-Menéndez, doctor en medicina, jefe de investigaciones del Instituto de fisiología y adscripto a la Cátedra de fisiología de la Facultad de ciencias médicas de Buenos Aires. Paper. Pp. 279, with 127 illustrations. Buenos Aires: El Ateneo, 1937.

For several decades following Laënnec's invention of the stethoscope there was a rich output of literature concerning the sounds of the heart. Experimental, clinical and postmortem observations were drawn on to explain the mechanism and meaning of normal and pathologic sounds. Since the advent of the x-rays and the electrocardiograph the subject has been presented from a new point of view. Graphic studies of the heart sounds by direct phonocardiographic methods and especially with electrical amplification have come to the front. This volume is the result of experimental and clinical study along these lines. Technic is described. The mechanism and graphic registration of normal sounds are well considered. In the last part more than a hundred pages is devoted to sounds in pathologic states—valvular lesions, gallop rhythm and various disturbances of rhythm. Many excellent illustrations, most of them original, help to explain the text. There is a good bibliography. The work is appropriately dedicated to Houssay and Wiggers. Whether the tendency to employ electrophonocardiography in everyday practice will develop until its use is widespread can only be determined by time. This book will be found a useful help by those interested in the subject.

X-Rays and Radium in the Treatment of Diseases of the Skin. By George M. MacKee, M.D., Professor of Clinical Dermatology, New York Post-Graduate Medical School and Hospital, Columbia University. Third edition. Cloth. Price, \$10. Pp. 830, with 310 illustrations. Philadelphia: Lea & Febiger, 1938.

This edition, almost entirely rewritten, amounts to a brand new, authoritative guide in the treatment of diseases of the skin with x-rays and radium. It embodies virtually all present knowledge of this subject and the book should be a "bible" for all dermatologists and for all other physicians, as well as technicians, who undertake the treatment of the various dermatoses with these agents. In order to reflect all aspects of the subject authoritatively, a noteworthy list of collaborators have written or brought down to date certain chapters of the book. These include new chapters on physics, biology, apparatus and instruments by Edith Quimby, a careful revision of the medicolegal chapter by Harold Bouton, an excellent and complete revision of the chapters on psoriasis, lichen planus and the hemopoietic diseases by Dr. Fred Wise, the action of roentgen rays and radium on animal organs and tissues by Dr. Arthur U. Desjardins, an excellent new chapter on histopathology by Dr. Hamilton Montgomery of the Mayo Clinic, a revision of the chapters on x-ray technic by Dr. Anthony Cipollaro, a complete revision of the chapter on fungous diseases by Dr. George M. Lewis, revision of the chapter on the pyodermas and other work by Dr. Henry D. Niles, and a thorough revision of the chapter dealing with miscellaneous disorders by Dr. Franklin Grauer. All obsolete material has been eliminated from this edition and it can be safely stated that it is practically impossible to offer any adverse criticism in the compilation of this excellent volume. Each chapter has a bibliography appended, from which the investigative student can readily obtain all the pertinent literature on any desired branch of the subject. The text is uniformly and concisely written throughout, and the style is uniform in spite of the rather large number of contributors. Credit is given where credit is due throughout the text. As stated.

this book has no competition and is now even much better in every respect than its previous editions; in fact, it is so far superior to its previous editions that no dermatologist, at least, can afford to be without it.

Recent Advances in Pathology. By Geoffrey Hadfield, M.D., F.R.C.P., Professor of Pathology in the University of London, and Lawrence P. Garrod, M.A., M.D., B.Ch., Professor of Bacteriology in the University of London. Third edition. Cloth. Price, \$5. Pp. 420, with 65 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1938.

The title of this book might well be changed to "Recent Advances in the Scientific Phases of the Practice of Medicine." Seventeen chapters cover in terse and easily understood language the newly acquired information on resistance to infection, the reticulo-endothelial system, cancer research and therapy, deficiency diseases, cardiovascular and renal diseases, the respiratory tract, the digestive system and liver, the central nervous system and the ductless glands. Every student of medicine, young or old, should be acquainted with the facts which are here so admirably condensed and clarified. Even recent graduates from medical schools may profit by such a review, and for older practitioners and those specializing in the laboratory divisions of medicine the book is a real *vade mecum*. As is inevitable in such a work, certain important omissions might be mentioned, particularly Goldblatt's work on experimental hypertension, recent developments concerning so-called vitamin K, the modern classification of the gliomas, and others which readers in various laboratories will conclude deserve more notice than has been given. However, it is doubtful whether any similar review in any phase of medical science will be found to be as complete as this one. The illustrations are carefully selected and splendidly reproduced. They are so valuable an adjunct to the text that readers would welcome more of them, particularly if colors could be used. A useful bibliography is given at the end of each chapter.

Poulsøn's Text-Book of Pharmacology and Therapeutics. Second English edition thoroughly revised by Stanley Alstead, M.D., M.R.C.P., Physician to Out-Patients at the Western Infirmary of Glasgow. Cloth. Price, 25s. Pp. 557, with 29 illustrations. London: William Heinemann, Ltd., 1938.

Poulsøn from 1895 to 1928 was a distinguished professor of pharmacology at Oslo. The eleventh edition of his text-book (in German) was published in 1937. It has been a popular textbook in Scandinavian and German universities for many years. The second revised English edition is based on the recent British and United States pharmacopœias. The plan followed is typical of "the continental atmosphere" and follows rather closely after Schmiedeberg's *Grundriss der Pharmakologie*. The book is perhaps too brief on the theoretic side and too limited in the discussion of recent developments. Ethylene, propylene and cyclopropane occupy but half a page, while curarine receives two pages. Acetylcholine is not mentioned, nor the adrenergic or cholinergic theories of nerve impulse. In the discussion of digitalis the chemistry is omitted and the term aglucone is not mentioned, and no mention of standardization is made. A mistake is made in the translation of β -imino azolyethylamine by calling it histidine instead of histamine, which might indicate that the translator did not desire to add to or emphasize the chemical side of the subject. In the discussion of acids, no mention is made of hydrogen ion concentration or acidosis. The discussion of ferments and foodstuffs is brief and hormones are not mentioned. The book as a whole is reliable and conservative but not so modern or inspiring as present conditions demand.

In the Name of Common Sense: Worry and Its Control. By Matthew N. Chappell, Ph.D. Cloth. Price, \$1.75. Pp. 192. New York: Macmillan Company, 1938.

The author began his professional career in engineering; later he became a Ph.D. in psychology and, because of his own neurosis, became interested in emotions. At present he is director of a private "group psychological research." According to the author, worry is a luxury and increases with practice and decreases with lack of practice. Exercises are presented to enable patients to shift from unpleasant to pleasant thoughts, thus breaking the habit of worry. Emotion can be

willed away. This book has been written for the lay person by a lay person whose only degree in academic psychology does not deter him from assuming the role of physician to the mentally ill. His lack of understanding of human psychologic problems and naïveté in his confidence seem colossal. Yet his therapeutic exercises carried out with neurotic groups may in short periods of time give help to a large group of patients unable to afford the time or expense of rational therapy, for his methods are those of reassurance and "covering up," particularly adapted in group therapy. Such a confident leader can sometimes exert a strong temporarily beneficial effect on neurotic groups.

Die Fasern des Nervus vagoaccessorius beim Menschen und bei Säugetieren. Von Doz. Dr. Julius Botár, Georg Popják und Dr. Alexander Bense. *Acta litterarum ac scientiarum Reg. Universitatis Hung. Francisco-Josephinae, Sectio medicorum*, Tome VIII, Fasc. 2. Redigunt: J. Baló, D. Miskolczy et St. Ruzsnyák. Paper. Price, 6.60 marks. Pp. 97-229, with 108 illustrations. Budapest: Eggenbergersche Buchhandlung Karl Rényi; Leipzig: Johann Ambrosius Barth, 1937.

This monograph is concerned with the anatomy, both gross and microscopic, of those nerve fibers which arise from the nervus accessorius and join with the vagus and which these authors have termed the nervus vagoaccessorius. The description of the structure of these nerves in the cat has been written by Bense, in the dog by Popják and in the monkey, chimpanzee and man by Botár. They conclude that the structure of these nerves as to the roots of origin, the main trunk and its branches does not differ materially in man and the various animals investigated.

On a New Gland in Man and Several Mammals (Glandula Parathyroides). By Ivar Sandström. [Uppsala Läkareförenings Förhandlingar, 1879-80, 15, 441-471.] Translated by Carl M. Sempel, Dr. Med. Dent. Edited by Charlotte H. Peters and J. F. Fulton. With bibliographical notes by Professor J. August Hammar. Boards. Price, \$1. Pp. 44, with 4 illustrations. Baltimore: Johns Hopkins Press, 1938.

Here is a careful translation of Sandström's pioneering work on the parathyroid, made by a fellow countryman who is now a graduate student in medicine. The article itself is of interest to all endocrinologists, histologists and anatomists. It is a classic contribution, for the first time completely translated from the Swedish. Combined with it is a biographic note by Prof. August Hammar, which includes a letter from Sandström to his sister describing the reception of presentation of this discovery at a scientific meeting and pertinent references to earlier work on the parathyroid. The book has been carefully edited by two persons thoroughly appreciative of medical history.

Las arritmias en clínica (diagnóstico, pronóstico y tratamiento). Por el Doctor Antonio Battro. Paper. Pp. 476, with 201 illustrations. Buenos Aires: El Ateneo, 1937.

This volume is much more than a reprint of the first edition of the author's work on the arrhythmias, published in 1933. There has been a thorough revision of the chapters on the theories of the irregularities, and the clinical features have been much expanded. The work is well gotten up, with numerous illustrations, especially of electrocardiograms that are of help in making clearer the meaning of the text. Diagnosis and treatment are given due prominence. Those who found the volume of 1933 of service will find this one still more helpful.

Nutrition of the Infant and Child. By Julian D. Boyd, B.S., M.S., M.D., Associate Professor of Pediatrics, State University of Iowa, Iowa City. National Medical Monographs. Edited by Morris Fishbein, M.D. Cloth. Price, \$3. Pp. 198, with 40 illustrations. New York: National Medical Book Co., Inc., 1937.

This monograph is an excellent summary of nutrition in pediatrics. The author writes as a physician who has not been swamped by the flood of foolishness poured out in commercial claims for various foods and vitamins. The critical and analytic spirit permeates this little volume chapter by chapter. The contents are divided into sections on the principles of nutrition, foods for the normal infant and child, and nutrition during illness. The text is well illustrated by reproductions of photographs. In a comparatively few pages at the end, practical diet lists and schedules are provided for a range from normal infant feeding to specific diabetic diets. The last section alone is

worth a place in any man's library for quick reference. In general, this little volume on nutrition in pediatrics is recommended to medical students and general practitioners. If properly interpreted by the glib group of the gossip school of food faddists, it constitutes a subtle rebuke.

Synopsis of Genitourinary Diseases. By Austin I. Dodson, M.D., F.A.C.S., Professor of Genitourinary Surgery, Medical College of Virginia, Richmond, Virginia. Second edition. Cloth. Price, \$3. Pp. 294, with 112 illustrations. St. Louis: C. V. Mosby Company, 1937.

This is an excellent compact presentation of practical phases of genito-urinary problems which should appeal to the student or busy practitioner. Current advances in the fields of calculi, malignant conditions, neurogenic disturbances and functional disturbances of the male sexual system bring the subject matter down to the present.

Miscellany

HEARING BY BONE CONDUCTION

GEORGE E. COLEMAN, B.S.
SAN FRANCISCO

People who are hard of hearing frequently complain that rapid strides are being made in the prevention and cure of many other diseases but "nothing is ever done for us." Deafness of whatever type presents one of the most baffling problems confronting medical science. Much has been accomplished in the past in the way of laying the foundations for accurate knowledge concerning the organ of hearing and the changes that occur in disease. Since the American Otological Society organized a research bureau and other smaller "funds" have provided grants to various universities, the pessimism is beginning to be dissipated. Otologists, anatomists, physiologists, neurologists, pathologists, psychologists, physicists and acoustical engineers have initiated well integrated programs either alone or in collaboration with one another and even between departments of different universities. Otologic research is now making stupendous progress, especially in the United States and Canada. During the International Congress of Otolaryngologists held at Prague the remark was frequently made that since American investigators are making such advances Europe will have to look to its laurels. The advent of the electrical hearing aid has proved a boon to those who are able and willing to use one. Many as yet refuse this boon and continue their complaints against science. This period will pass; in the years to come more millions will accept this aid. First came reception by air conduction, then by bone conduction. Each has brought in its train new medical and physical problems which are now receiving intensive investigation. I refer chiefly to the standardization of audiometers, to possible injury due to excessive amplification of air borne sounds, and to possibilities of reeducation, by the judicious use of a proper instrument, either of a not too degenerated or damaged end organ in the cochlear duct or of receptors for hearing in the brain. The time is not yet here, however, when salesmen of hearing aids should permit themselves to discuss these matters pseudoscientifically with prospective clients.

The phenomenon of hearing by bone conduction has been known for many centuries. Recently a wide interest in the subject and its more technical problems has become awakened. The attention given to bone conduction during the meeting of the American Otological Society in Detroit in May 1936 did much to stimulate interest.

Especially new are some painstaking studies which occupied three years, made by Norman Watson¹ in the laboratory of

Professor Knudsen in the University of California. After a comprehensive survey of previous investigations and the types of vibrators used in them, a special induction type electrodynamic vibrator of wide frequency range and large output, linear in response and as free as possible from stray sound radiation, was designed and built. This was combined with a suitable driving system and calibrations were then obtained on both by apparatus specially designed for the purpose. Then a few of the problems of hearing by bone conduction were studied.

One of the problems to which Watson has given consideration concerns cranial resonance and a study of the vibrating skull. The cranium has been found to vibrate somewhat like an elastic spherical shell at 1,000 cycles but to deviate from such vibrations in certain particulars. The relative magnitudes of vibration at different portions of the skull have been determined. While injury to the inner ear from cranial resonance at high intensities seems possible, Watson believes that such injury is not apt to be caused by the less intense vibrations produced by commercial hearing aid bone conduction units.

A method of determining bone conduction thresholds has been developed which is capable of high accuracy. In the case of one observer, at a single frequency, a series of measurements has been obtained with an average error of a single observation of only 1.1 decibels. This is decidedly encouraging. I have had frequent hearing tests over a period of years by different observers using the same audiometer and by the same observer using different instruments and there have been wide fluctuations in the results, beyond the probability of corresponding changes in hearing threshold. An eminent European otologist who recently visited this country stated that, until audiometers are more carefully standardized, more accurate determination of hearing threshold could be obtained with tuning forks. Watson has studied the threshold at various positions on the skull and teeth under varying conditions and has determined that bone conduction hearing is most acute when the mouth is closed, the teeth are clenched and the ear canals are occluded. The lowering of the threshold on occlusion of the ear canals has been found to be a real phenomenon at frequencies as high as 10,000 cycles.

The effect of certain factors, such as the total force of the vibrator button on the skin and the size of the button, have been determined and correlations made between the positions of maximal vibration on the skull and positions of the vibrator to give the greatest acuity. For the present at least the amplitude of vibration of the vibrator button, placed on the center of the forehead, has been found to be the most satisfactory unit of measurement of bone conduction thresholds, although the actual acuity at this position is 10.5 decibels lower than when the vibrator is placed on the upper teeth.

Other problems studied by Watson are the tentative determinations of the limits of audition of pure tones by bone conduction (open ear canals), both as to usable intensity range and as to the total frequency range. A method for testing the hearing of speech by bone conduction has been developed which is based on that of Fletcher and Steinberg for air conduction testing. Application of this method to Watson's own hearing (slightly above average) indicated that for all levels above threshold up to 85 decibels the articulation was the same whether he listened by air conduction (one ear or two) or bone conduction (open or occluded ear canals). This points to the conclusion that the hearing of speech by bone conduction may attain as high a degree of perfection as that attained by the more usual method of air conduction.

With these and the continuing studies on selective amplification in the laboratory of Dr. Knudsen and active research elsewhere, the hard of hearing as a group may well take further encouragement.

¹From the Hooper Foundation, University of California.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Hospitals: Right to Determine What Physicians May Perform Surgery on Premises.—The Marlboro County General Hospital was established and maintained from funds solicited from the public at large. The trustees of the hospital, who were selected by the contributors, procured a charter from the state and adopted rules for the regulation and control of the hospital. The appellant, a licensed physician, alleging that those rules deprived him of the privilege of practicing surgery in the hospital, sought by legal action to have the hospital declared a public hospital and to require the trustees to revoke the rules which excluded him from practicing in it. The trial court dismissed the action, and the physician appealed to the Supreme Court of South Carolina.

It is conceded, said the court, that if the Marlboro County General Hospital is a private institution the action instituted by the appellant must fail. The court held that the hospital, although a public charity, was a private corporation, and quoted from *Dartmouth College v. Woodward*, 4 Wheat. 518, 671, 4 L. Ed. 629, as follows:

When, then, the argument assumes, that because the *charity* is public, the *corporation* is public, it manifestly confounds the popular, with the strictly legal, sense of the terms. . . . When the corporation is said, at the bar, to be public, it is not merely meant, that the whole community may be the proper objects of the bounty, but that the government have the sole right, as trustees of the public interests, to regulate, control and direct the corporation, and its funds and its franchises, at its own will and pleasure. Now, such an authority does not exist in the government, except where the corporation, is in the strictest sense, public; that is, where its whole interests and franchises are the exclusive property and domain of the government itself.

The action of the trial court in dismissing the physician's complaint was accordingly affirmed.—*Strauss v. Marlboro County General Hospital* (S. C.), 194 S. E. 65.

Optometry: Corporate Practice of Optometry Illegal; Injunction to Restrain Practice.—The defendants, a firm of opticians, sold eyeglasses on prescriptions by registered physicians and optometrists. Most of the prescriptions filled by the defendants were issued by a physician employed by them in their place of business at a weekly salary. The price charged was the same whether the customer brought his own prescription or obtained one from the physician employed by the defendants. The price was retained in whole by the defendants. The plaintiff, a registered optometrist, "for his own benefit, for the benefit of other optometrists, and for the benefit of the public," brought suit to restrain the defendants from practicing optometry without being registered under the optometry practice act of Massachusetts. The case was reported, without decision, to the Supreme Judicial Court of Massachusetts on an agreed statement of facts.

The optometry practice act of Massachusetts provides that in order to practice optometry a person must possess certain educational qualifications, pass an examination and be registered. Physicians and surgeons lawfully entitled to practice medicine in the state are exempted from the provisions of the act. The defendants contended that they were not practicing optometry illegally because their servant, who was a physician, was entitled to practice optometry without registration.

There is, said the Supreme Judicial Court, a generally recognized rule that a licensed practitioner of a profession may not lawfully practice his profession as a servant of an unlicensed person or a corporation and, if he does so, the unlicensed person or corporation employing him is guilty of practicing that profession without a license. A corporation cannot possess the personal qualities required of a practitioner of a profession. Its servants, though professionally trained and duly licensed to practice, owe their primary allegiance and obedience to their employer rather than to the clients or patients of their employer. This rule recognizes the necessity of immediate and unbroken

relationship between a professional man and those who engage his services. It has been applied to lawyers, physicians and dentists. While recognizing a conflict of authority, the court was of the opinion that the greater weight of authority held that optometry constitutes a profession rather than a trade. Abnormalities of the eye sometimes indicate and often result in serious impairment of the general health. The learning and the ethical standards required for optometry and the trust and confidence reposed in optometrists by those who employ them cannot be dismissed as negligible or as not transcending the requirements of an ordinary trade. In this connection the court pointed out that section 72 of the optometry practice act of Massachusetts declares that "No optometric practise or business . . . shall be conducted under any name other than that of the optometrist or optometrists actually conducting such practise or business." The court interpreted this provision to prohibit, as a general rule, the practice of optometry by a layman or a corporation through servants who are registered optometrists. An exception to the general rule in the statute, which provides that the statute shall not "prevent the employment by any person of a registered optometrist to be in charge of, or practice optometry in, an optical department conducted by such person," was not applicable to the case in question. The servant employed by the defendants did not come within that exception because he was not a registered optometrist but a physician. The court therefore concluded that the defendants were practicing optometry without right.

Accordingly, a decree was granted restraining the defendants from practicing optometry, either personally or by any servant or employee, until they should become lawfully entitled to do so.—*McMurdo v. Getter* (Mass.), 10 N. E. (2d) 139.

Workmen's Compensation Acts: Hemorrhage into Eye in Relation to Strain and Tuberculosis.—In the course of his employment the claimant drew off seed beans from a hopper into sacks and then piled the sacks, each weighing from 112 to 150 pounds, on a truck, the top sack being placed at a height of from 3½ to 4 feet. On Dec. 27, 1935, after he had stooped to lift one of the sacks he noticed that objects appeared red when he looked at the light and it seemed as if there were red streaks "of stuff" through his left eye. When he did not look at the light "it looked like a bunch of moss wove around through" the eye. Three days later he consulted an eye specialist, who found "an extensive recent hemorrhage on the interior of his left eye," with approximately 80 per cent impairment of vision of that eye. His right eye was practically normal. The claimant continued at work and on January 9 his physician found a hemorrhage in the right eye also. Shortly thereafter roentgenograms disclosed an old healed tuberculosis in his lungs. The impairment of vision grew progressively worse and eventually the claimant became permanently and totally blind in both eyes.

In the course of the proceedings instituted by the claimant under the workmen's compensation act of Wyoming there was medical testimony to show that the walls of the blood vessels in his eyes had been weakened by the old tuberculosis; that strain, lifting, walking hard, jarring the body or even excitement would produce such hemorrhages as he sustained; that the strain of lifting the sacks in the course of his employment would be such as would cause the hemorrhages; that a person suffering from weakened blood vessels in the eye as a consequence of an old healed tuberculosis might safely go through life without any impairment of vision if he was careful in all physical movements, and that a person of the claimant's age, if the blood vessels in his eyes were normal, would not be affected by hard labor or the strain of lifting sacks such as those he lifted. All the physicians who testified at the trial agreed that a person would notice a hemorrhage into the eyeball within a few seconds after it occurred, as when such a hemorrhage takes place "the light of any light appears red." There was no definite evidence, however, regarding the time when the claimant first noticed hemorrhages in his right eye. The trial court found that the strain in lifting the sacks caused the bursting of the blood vessels of his eyes and that he had sustained a compensable accident under the Wyoming workmen's compensation act. He

was awarded compensation for permanent and total blindness in both eyes and the employer appealed to the Supreme Court of Wyoming.

The employer contended that there was not sufficient evidence on which to base the finding that the claimant suffered an accidental injury on Dec. 27, 1935, as a result of his employment, because his blindness was caused by disease not ensuing from any injury suffered in his employment and he was doing only his usual work when the difficulty occurred. The Supreme Court, however, concluded that the claimant had suffered a compensable accidental injury and that, so far as the right to compensation was concerned, the fact that the blood vessels in the claimant's eyes were abnormally weak, whether congenitally or from disease, made no difference. Compensation, said the Supreme Court, under the Wyoming compensation act does not rest on the condition of health of the employee or on his freedom from liability to injury through a constitutional weakness or latent tendency. The Supreme Court concluded, however, that the trial court erred in making the award when it took into account the condition of the claimant's right eye, since there was no testimony to indicate when the hemorrhage in it occurred. The burden was on the claimant to show that he suffered a compensable injury in the right eye before an award could be legally made for such an injury.

The Supreme Court accordingly affirmed the judgment of the trial court so far as it awarded compensation for loss of vision in the left eye and reversed it so far as it undertook to make an award for the loss of vision in the right eye. The court directed a new trial of the issues as to the injury to the right eye.—*In re Scroggum: Associated Seed Growers, Inc., v. Scroggum (Wyo.)*, 73 P. (2d) 300.

Medical Practice Acts: Issuance of License Without Examination Discretionary with Licensing Board.—Section 924 of the Delaware code, a section of the Delaware medical practice act, requires the medical council to license an applicant who has passed an examination given by the appropriate board of medical examiners. It provides that the medical council may, on the recommendation of the board of medical examiners, without further examination, license an applicant who has been examined and approved by the National Board of Medical Examiners and has complied with certain other conditions not here material. A certificant of the National Board of Medical Examiners instituted mandamus proceedings against the medical council to compel it to license her, without examination, to practice medicine. She contended that it was the duty of the medical council to license an individual who had been examined and approved by the National Board of Medical Examiners, claiming that the word "may," italicized above, meant "must" or "shall" and was not used in a permissive sense. The superior court of Delaware, New Castle, however, concluded that the legislature intended to give the medical examining boards and the medical council discretionary powers with respect to applicants who have not passed the usual examinations. The petition for a writ of mandamus was therefore dismissed.—*State ex rel. Foulger v. Layton (Del.)*, 194 A. 886.

Workmen's Compensation Acts: Sarcoma of the Sternum Attributed to Trauma.—The deceased, a janitor, in the course of his employment in the spring of 1935, stumbled. His chest struck a box he was carrying and the box defaced a desk top, but although he reported the incident to his superior he did not mention the fact he had hurt himself. That night, however, he told his wife of the occurrence and complained that "his chest was hurting him awful bad," but he continued to work. About three weeks later his wife noticed a red spot on his chest about the size of a dollar. He then consulted a physician, who described the injury as "a hard protuberance, tumor like." Shortly thereafter the deceased informed his employer of his injury. For about fourteen months longer the workman continued at work. The protuberance continued to grow. In March 1936 roentgenograms showed a growth on the chest and bone destruction of the breastbone and cartilages of the ribs. Apparently a diagnosis of sarcoma of the sternum was made at that time. On June 6, 1936, the growth, which had developed to the "size of a baby's head," was removed by

surgery. Thereafter the workman was confined to bed until his death in September 1936. Compensation was awarded to his widow under the Kansas workmen's compensation act, and the employer and his insurance carrier appealed eventually to the Supreme Court of Kansas.

His widow testified as to what the deceased told her when he returned home from work on the night when the accident was alleged to have occurred. The attending physician testified that the fall and injury, in his opinion, caused the condition that eventually developed into a sarcoma of the breastbone. The physician who had taken the roentgenograms of the deceased's chest in March 1936 testified that the tumor could have come from the injury in the spring of 1935. The physician who removed the growth from the deceased's breastbone testified that the tumor resulted from the injury. Nevertheless the employer and insurance carrier, appellants, contended that there was no competent evidence that an accident in the course of the deceased's employment caused his death and called an expert witness who testified that "sarcoma malignancies" are not traceable to trauma in more than 2 per cent of the cases or even less; but he added:

The important thing is the establishment of the fact of a trauma, and finding within this tissue or that immediately adjacent to the . . . periosteum and the structure of the bone or immediately adjacent to the point of the alleged injury, evidence of the injury. If in such a tissue anywhere from four weeks to a year or even more a malignancy develops, I believe it would be considered due to trauma.

The Supreme Court of Kansas held that the evidence was sufficient to prove the occurrence of the accident and its causal relation to the death.

The appellant assigned error in the admission of the testimony of the widow as to what the deceased had told her the night he was hurt. The admissibility of evidence before the compensation commission, said the Supreme Court, is to be governed not by the venerable rules of evidence but under the liberal rules applicable to hearings before that commission. The courts may not nullify the commissioner's work by applying their own standards to it; if the commissioner's decision is based on substantial and satisfactory evidence, relevant, reasonable and persuasive, though not technically admissible under the rules of evidence governing procedure, the decision will be upheld. The true rule as to the admissibility of the evidence before the compensation commission, the court thought, was as follows: Where a workman dies of his injuries, the statements he made to third persons touching the accident which caused his injuries may be received and accorded probative force, if such statements are inherently reasonable and not intentionally made for the purpose of being used as evidence to base a claim for compensation, and where the other evidence and attendant circumstances corroborate the statements so convincingly as to establish the fact of the workman's accident and injury with moral certainty. Tested by this rule, said the Supreme Court, the testimony of the widow was properly received.

The award of compensation in favor of the widow was accordingly affirmed.—*Parker v. Farmers Union Mut. Ins. Co. (Kan.)*, 73 P. (2d) 1032.

Society Proceedings

COMING MEETINGS

- National Medical Association, Hampton, Va., Aug. 15-19. Dr. John T. Givens, 1108 Church St., Norfolk, Va., General Secretary.
- Oregon State Medical Society, Timberline Lodge, Aug. 24-27. Dr. Morris L. Bridgeman, 1020 S.W. Taylor St., Portland, Secretary.
- Society of American Bacteriologists, San Francisco, Aug. 30-Sept. 1. Dr. I. L. Baldwin, College of Agriculture, University of Wisconsin, Madison, Wis., Secretary.
- Utah State Medical Association, Ogden, Sept. 1-3. Dr. D. G. Edmunds, 610 McIntyre Bldg., Salt Lake City, Secretary.
- Washington State Medical Association, Bellingham, Aug. 29-31. Dr. V. W. Spickard, 1303 Fourth Ave., Seattle, Secretary.
- West Virginia State Medical Association, White Sulphur Springs, July 11-13. Mr. Joe W. Savage, Public Library Building, Charleston, Executive Secretary.
- Wyoming State Medical Society, Laramie, Aug. 7-9. Dr. M. C. Keith, 156 South Center St., Casper, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1928 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

15: 515-642 (May) 1938

*Comparison of Percussion and Radiography in Locating the Heart and Superior Mediastinal Vessels. D. Mainland and C. B. Stewart, Halifax, N. S., Canada.—p. 515.

*Injection Plus Dissection Study of Coronary Artery Occlusions and Anastomoses. M. J. Schlesinger, Boston.—p. 528.

Role of Nutritional Deficiencies in Production of Cardiovascular Disturbances in the Alcohol Addict. R. Goodhart and N. Jolliffe, New York.—p. 569.

Study of Myocardial Hypertrophy of Uncertain Etiology, Associated with Congestive Heart Failure, with Consideration of Role of Antecedent Hypertension. B. I. Kaplan, E. Clark and C. E. de la Chapelle, New York.—p. 582.

Abnormal Distribution of Superficial Muscle Bundles in the Human Heart. Jane Sands Robb and R. C. Robb, Syracuse, N. Y.—p. 597.

Effect of Digitalis on Form of Human Electrocardiogram, with Special Reference to Changes Occurring in the Chest Lead. H. J. Stewart and R. F. Watson, New York.—p. 604.

Percussion and Radiography.—Mainland and Stewart studied by percussion the deep dulness of the heart and the superior mediastinal vessels of 110 male university students when erect and when recumbent. Wire markers were then fastened to the chest and telerradiographic films were taken. All results were analyzed statistically. In these students the mean errors (difference between percussion and x-ray borders) were less than 1 cm. in most intercostal spaces; but much greater allowance for possible error had to be made in percussion of any one subject; for example, there was a range of more than 3.5 cm. in the fourth left intercostal space in students in the erect position. The differences in error between the erect and the recumbent position could be largely attributed to dispersion of x-rays. For practical purposes the variation between two percussions on the same student was as great as between different students, because the correlation between the errors in repeated percussions of the same students, although significant, was low. From one third to one half of the variation in the cardiac (but not the superior mediastinal) region was attributable to diaphragmatic movement, it being impossible to secure the same midphase of respiration on any two occasions. The risk of wide error in any individual percussion could be greatly lessened by taking the average of several independent readings, thereby reducing the effect of diaphragmatic movement. Stature, weight and size or shape of the chest had no important relation to the percussion error. Ten students, taken at random, sufficed to show the difference in error of two experienced physicians. Each observer should know his own percussion error.

Coronary Artery Occlusions and Anastomoses.—To ascertain accurately the site and effects of all occlusions and anastomoses of the coronary artery in individual hearts Schlesinger found that it was necessary to devise a method capable of completely and simultaneously visualizing the entire course of all arterial branches so that they could be studied in detail. This has been accomplished by a simple standardized method utilizing (1) a newly devised multicolored radiopaque injection mass, (2) a new method of cutting open the injected heart and (3) a complete dissection of the colored coronary artery tree. The new injection mass consists of a suspension of lead phosphate in agar, colored differently for the right and left coronaries. It is injected at 150 mm. of mercury pressure, at 45 C.; it sets quickly and permits immediate cutting and roentgenography of the fresh unfixed heart. The new method of opening the heart unrolls all the coronary arteries so that they lie in one plane and avoids overlapping of the roentgenographic shad-

ows of the injection mass within them. The distribution of the multicolored mass in the branches of the dissected coronary artery gives an absolute index of the distribution of the blood from either orifice of the coronary artery.

American Journal of Diseases of Children, Chicago

55: 897-1140 (May) 1938

*Rheumatic Erythema Nodosum. A. Wallgren, Göteborg, Sweden.—p. 897.

Metabolism and Mode of Action of Vitamin D: III. Importance of Liver for Its Antirachitic Efficacy. W. Heymann, Cleveland.—p. 913.

Diagnosis of Syphilis in Newborn Infants: Use of Quantitative Wassermann Tests. A. U. Christie, Baltimore.—p. 979.

Mentality of Infants Relieved of Hydrocephalus by Coagulation of Choroid Plexuses. T. J. Putnam, Boston.—p. 990.

Pathology of Chronic Arthritis of Children (Still's Disease). R. B. Portis, Chicago.—p. 1000.

The Undescended Testicle. N. Nixon, Los Angeles.—p. 1037.

Rheumatic Erythema Nodosum.—Wallgren points out that investigators have been disinclined to give up the idea that in certain cases there may exist a connection between erythema nodosum and rheumatic fever, even though in general erythema nodosum rests on a tuberculous basis. A rheumatic etiology is quite compatible with the present conception of its pathogenesis. Rheumatic erythema nodosum should, in the first place, be sought among those who react negatively to tuberculin. In certain cases existing tuberculous infection need not be the cause of erythema. For instance erythema nodosum following an attack of tonsillitis in a tuberculous child may be due to the tonsillitis and may have no connection with the tuberculous infection. In such a case, however, strong reasons should be adduced in support of the assumption that the tuberculosis is not the producer of the erythema, and the first condition is to prove that the tuberculous infection is inactive and obviously older than the erythema. Tuberculous erythema usually occurs when the tuberculous infection manifests itself. The only cases in which a genesis other than tuberculosis can be proved are those in which the reaction to tuberculin remains negative during other acute infections. Hence it follows that one may consider rheumatic fever as the cause of erythema nodosum only on condition that the child is not infected with tuberculosis. For the correct interpretation of the pathogenesis of the erythema a child should always be examined for tuberculosis when he has acute rheumatism during which erythema nodosum appears.

Collapse Therapy in Tuberculosis.—Siegel and Singer present the results obtained by artificial pneumothorax and by other means of collapse therapy employed between 1928 and 1936 for 105 children from 5 to 15 years of age with open pulmonary tuberculosis. The sputum of all these children contained tubercle bacilli, and a cavity was visible in the roentgenogram in 95 per cent of the cases. The predominant clinical types seemed to have begun either as isolated infiltrative tuberculosis, usually in the infraclavicular region with a tendency to cavitation and bronchogenic dissemination, or as bilateral disseminated tuberculosis, apparently the sequela of a benign hematogenous seeding, with a tendency to the formation of nodular-cirrhotic productive lesions with or without small cavities. In addition, there were far advanced bilateral forms, usually with bilateral cavities. Forty children improved, thirty-three remained unimproved and thirty-two died. Conversion to negative sputum was obtained by means of pneumothorax alone in twenty-one of twenty-eight children within three months and in all twenty-eight children within six months after the start of collapse therapy. Moderate or large amounts of pleural effusion developed in the course of pneumothorax in twenty-eight cases. Tubercle bacilli alone were found in nine cases, pyogenic organisms and tubercle bacilli in four cases and pneumococci in one case. The fluid was resorbed in only two of the thirteen cases in which either tuberculous or mixed infections were present. After collapse therapy, 60 per cent of the patients with isolated infiltrative tuberculosis (unilateral) improved, of those with infiltrative tuberculosis (with contra-

lateral spread) 22 per cent improved and 29 per cent of those with disseminated tuberculosis improved. With a small amount of collapse (less than 50 per cent) 15 per cent of the patients improved, with a moderate amount (from 50 to 75 per cent) 30 per cent improved and with a large amount (over 75 per cent) 50 per cent improved. The best results were obtained among the children with unilateral isolated infiltrative tuberculosis in whom a large amount of collapse could be obtained. Regression of the contralateral process was seen in only 12 per cent of the cases in which bilateral lesions were treated on one side only, while progression occurred in 53 per cent of these cases. Unilateral collapse therapy is inadequate in such cases and collapse on both sides is required. By means of bilateral collapse therapy the number of improved children increased. Internal pneumolysis, in patients with broad, extensive adhesions, was rarely successful and was attended with considerable danger. Several children improved after thoracoplasty. Most of the deaths among the treated children occurred within the first two years after the initiation of therapy, after which relatively few children died. Most of the deaths were due to the progression of the disease on the contralateral side or because the process was too far advanced at the start of therapy. Of eighty-seven untreated children with open lesions admitted to the hospital between 1929 and 1936 and observed to date 95.4 per cent died, 1.1 per cent are unimproved and 3.4 per cent are improved.

Pellagra in California.—A questionnaire form has been sent by the California State Department of Public Health to each physician in the state reporting a case of pellagra since 1928. Of 627 cases reported as pellagra from 1928 to 1935 Smith and Stevens chose 520 for analysis. The criterion for inclusion was the presence of a dermatitis compatible with this diagnosis. Pellagra reported in California has been of the severe type, as is shown by the high incidence of diarrhea, oral lesions, dementia or other manifestations of the nervous system. Dementia and other symptoms of the nervous system occurred most frequently in the alcoholic patients. Only one tenth of the cases were recurrent, and recurrences were approximately three times greater in dietary than in alcoholic pellagra. Morbidity rates increased progressively from youth to old age with a mean age of 49.79 ± 0.43 years. One half of the cases occurred in the 40 to 59 age group. There were twice as many male as female pellagrins in the alcoholic group but in the other classifications there were more females than males. Pellagrins of native white stock born in California were mainly addicted to alcohol, while those born in other states were for the most part in the dietary deficiency and antecedent illness groups. One half of the cases developed during the four months February through May. The disease was predominantly urban, and the cheap rooming house sections of the cities contributed the majority of the cases. The approximate mortality was 66 per cent; patients more than 50 years of age had the highest. Of the 146 pellagrins with dementia, diarrhea and oral lesions 92 per cent died.

Mortality and Longevity in Diabetes Mellitus.—Joslin and his associates constructed life tables based on diabetic patients treated at the Baker Clinic from 1897 to 1928 and traced to 1929. The tabulations have been made in the same manner as those in insurance work. There has been a continuous decline in the death rate of diabetic patients. The death rate at all ages in the latter part of the period surveyed, 1926 to 1929, was 75 per cent below that of the first part, 1897 to 1913. The gains have been greatest in young diabetic patients. The decline in mortality was most rapid after insulin came into use. Large increases in the expectation of life have occurred. At the age of 10, the increase between 1897-1913 and 1926-1929 is estimated at about thirty years. The increase is progressively less with advancing age. The death rate in diabetes is still much in excess of that for the general population.

Lead in Blood of Normal Human Subjects.—Scott and McMillen examined spectrographically samples of blood of eighty-nine normal first year medical students for traces of lead. Forty-four blood samples failed to show traces of lead in quantities of 0.001 mg. or more per hundred cubic centimeters. The other forty-five samples of blood contained from 0.001 to 0.009 mg. of lead per hundred cubic centimeters of whole blood.

Fatigue and Monocytosis in Neutropenia.—In order to determine the relative importance of etiologic factors Reznikoff studied the thirteen cases of neutropenia admitted to the hospital during the last five years. Fatigue previous to the onset of illness was found to be a prominent predisposing factor in eleven of the thirteen cases. No inquiry was made as to this fact in two cases. Drugs were known to be of etiologic significance in nine cases and in the other four no evidence of drug administration could be elicited. Menstruation was a factor in the case of three of the nine female patients; six women had passed the menopause. Infection was of possible etiologic importance in six cases; in four no history of infections could be elicited and in three no previous infection was found. Analysis emphasizes the importance of fatigue as a precursor to neutropenia when this factor is considered. A perusal of the literature indicates many cases of agranulocytosis in which fatigue, worry and sleeplessness were sufficiently marked to call the attention of the physician to this factor. Of the thirteen patients, nine recovered, and all had sustained relative, and in most cases absolute, monocytosis. In many of the cases an increase of monocytes preceded the return of neutrophils, the rise in leukocyte count, the drop in temperature or the symptomatic improvement. Two of the four patients who died showed a progressive decrease in monocytes and one was reported to have had an

increase from 0 to 20 per cent just before death. The fourth patient presented an atypical picture. The clinical diagnosis at necropsy was aplasia of the bone marrow or acute leukemia and chronic neutropenia. Two days before death a count of 30 per cent monocytes was reported. The patients who recovered had monocyte peaks ranging from 17 to 66 per cent and in all cases the monocytosis was sustained for several days. To be significant monocytosis must occur early in recovery and persist.

Dermatoses Due to Vitamin A Deficiency.—During the last two years Youmans and Corlette observed a number of patients with an eruption which they believe is due to vitamin A deficiency. Twenty cases have been studied in detail. So far as the authors are aware, their cases are the first instances in white persons to be reported in this country. In most of these this deficiency was due simply to an inadequate diet. In a few cases the deficiency was conditioned by disease leading to a decreased intake, an improper absorption or an increased demand for the vitamin. The horny or gooseflesh type of eruption, the similarity of the lesions, grossly and histologically, to those described by Frazier and their response to treatment with vitamin A identify these conditions as a specific dermatosis due to vitamin A deficiency. Grossly, the individual lesions resemble in many, but not all, respects the acne papule, with the important exception as noted by Loewenthal and by Frazier and Hu, that pustulation is uncommon. The eruption has occurred in adults well past the acne age, without a history of or scars of preexisting acne, and the affected areas (arms, legs and back) are those less commonly involved by acne. Histologically, the lesions have differed from the other type only in a slightly greater cellular reaction. The eruption has disappeared following the administration of vitamin A. Although the changes in the eye and in vision have been thought to be the earliest reliable clinical manifestations of vitamin A deficiency, the authors' observations as well as those of Frazier and Hu suggest that in some instances the cutaneous eruption may be the first clinical evidence of the deficiency. These changes are easily recognizable. The time required for the eruption to disappear under the influence of treatment with vitamin A is of practical importance. Improvement is seldom noted in less than four weeks, and in many instances from twelve to fourteen weeks is required before the eruption has disappeared. The prolonged response of the eruption to treatment is a factor which must be taken into consideration when the response to treatment is considered in the diagnosis.

Blood Pressure of Infants.—Woodbury and his colleagues carried out the present study in order to measure accurately the blood pressure at birth, to establish a reliable method for clinical use in measuring the blood pressure of the newborn, to study the effect of certain drugs and to record the pressure changes that occur under various physiologic and pathologic conditions. Thirty-seven babies were observed: twenty-four were apparently normal, the mothers of eight of the infants had toxemias of pregnancy and five infants were prematurely born. The blood pressures, with the use of the hypodermic manometer, of the twenty-four full term babies averaged 80/46 mm. of mercury. The standard deviation of a single observation was 8.1 mm. (systolic) and 8.2 mm. of mercury (diastolic). The infant's blood pressure was not significantly affected by obstetric anesthesia, by the onset of respiration, by the clamping of the cord after birth or by the administration of carbon dioxide and oxygen to the baby. The infant's blood pressure was affected slightly but significantly by the blood pressure level of the (normal) mother, by toxemia of pregnancy in the mother, by amyl nitrite administered to the baby and by 0.2 mg. of epinephrine administered intravenously. It was markedly affected by crying, by dehydration without collapse, by administration of fluid to the dehydrated baby and by the degree of prematurity.

Age and Blood Pressure.—Lewis determined the blood pressure of 100 men, twenty in each decade from 40 to 89 years of age. There was also a man of 91 and one aged 101. The measurements were made with a mercury manometer by the auscultatory method. The subjects were in a basal state—at rest in bed, in the morning, having fasted fourteen hours. The systolic pressure rose continually after the age of 40, but the greatest rise was observed after the age of 65. At the age of from 40 to 44, the average pressure was 116 mm.; at the age of from 60 to 64 it was 124 mm. At the age of from 85 to 89 it was 158 mm. For the two men over 90 the pressure was actually lower. The scatter of individual measurements was greater in the older groups than in the younger. The deviation from the mean in the various age groups was somewhat greater in the elderly. The largest standard deviation was 26.5 mm. in the men aged from 85 to 89 years, the smallest 8.4 mm. in those aged from 45 to 49. The level of the median of the systolic pressure increased gradually with age. The level of the mean of the systolic pressure rises with increasing age. The general trend of the systolic pressure is a rise and is directly related to age. But the mean values, if taken by five or ten year periods, present not a straight line relation but a curvilinear one. There is first a gradual rise from 40 to 64 years and then a rapid rise from 65 to 89 years. After 89 years there

is apparently a fall. The average diastolic pressure varied slightly in succeeding decades. The mean value in the five year groups ranged from 75 mm. of mercury (at from 65 to 69 and 70 to 74 years) to 85 mm. (from 80 to 84 years); in the ten year groups it varied between 75 and 80 mm. The extent of scatter was approximately the same at all ages; it was smallest in the period from 40 to 49 years. The standard deviation, ranged from 6.4 mm. (8.2 per cent) to 12.8 mm. (15.5 per cent). The standard deviation was smaller at ages 45 to 54 years than in other groups. The relation to age follows an uninflected horizontal line. The average mean pressure in succeeding five and ten year classes presented an increase with age. The rise was similar to that of the systolic pressure but modified by the constancy of the diastolic pressure. The average mean pressure in those aged from 40 to 44 years was 96 mm. A slight rise occurred up to 55 years, a more marked rise after 75 years. As with the systolic and the mean pressures, the relation of the pulse pressure to age is represented more accurately by a curvilinear regression with significant inflections beginning at the sixtieth year.

The Ayala Index.—Savitsky and Kessler analyzed the clinical value of the Ayala index, on the basis of 186 readings in 181 cases in which cerebrospinal fluid hypertension measured at least 140 mm. of water. The Ayala index is usually computed as the product of the final intracranial pressure and the amount of spinal fluid removed divided by the initial pressure. Like any other method of investigation, the index is merely an aid and cannot be considered as a conclusive diagnostic procedure. It must be evaluated in the light of all the other signs. Indexes of between 1 and 5 favor the diagnosis of an expanding lesion, such as tumor or abscess. Indexes of between 5 and 6 are equivocal and cannot help in deciding between hydrocephalus and an expanding lesion. When the index is above 6.5 one is probably not dealing with an expanding lesion. The quantity of spinal fluid removed should be constant—the authors suggest 10 cc. Expanding lesions tend to produce low indexes and all other groups high indexes. The index has been found to be of greatest value in the diagnosis of abscess of the brain, especially in its differentiation from otitic hydrocephalus. The Ayala index has been helpful in diagnosis in more than 90 per cent of the cases. The results in the series have been constant. The Ayala index is of no value in the diagnosis of tumor after operation. The indexes in the postoperative series were almost all high; when preoperative indexes were available they were always relatively low. From a few cases of subdural hematoma it was learned that when the Ayala index is over 7, or even over 6.5, the likelihood of a subdural hematoma is less. In 87 per cent of forty-one cases of hypertensive vascular disease, the Ayala index was above 5.5. The index is of especial value in such cases, for occasionally an expanding lesion coexists with hypertensive vascular disease. When the Ayala index is low,

especially below 5, it is probable that a tumor of the brain with hypertensive vascular disease exists. A high Ayala index is found in cases of uncomplicated arterial hypertension associated with increased spinal fluid pressure.

Acute Retrocecal Appendicitis.—During the last ten years, Collins has encountered 751 instances (25 per cent) of acute retrocecal appendicitis among 3,003 consecutive appendectomies. Four hundred and seventy-one of the patients were men. The average age of the 751 persons was 29.7 years. Three hundred and one mentioned previous frequent occurrence of infections of the upper part of the respiratory tract, and in 111 of these such infections had preceded their present acute abdominal complaints by an average interval of 8.4 days. Four hundred and sixty-six persons had had previous similar attacks of abdominal pain of varying degrees of severity. Three hundred and eight patients had been previously treated for cholecystitis, gastric or duodenal disease or for disease of either the right kidney or the right ureter. Fifty-two persons had been operated on for various types of peptic ulcer, without alleviation of their symptoms. Of the 280 women in the series, forty-four had received medical treatment for pelvic inflammatory disease without obtaining noticeable relief. At the time of the appendectomy, thirty-three showed no evidence of pelvic inflammatory disease. Two nephropexies had been performed without relieving the patients. Forty-five women had been subjected to various gynecologic procedures, without experiencing permanent relief. An additional thirty-one had had various major pelvic operations, at which, for various reasons, their appendixes had not been removed. Nausea, headache, flatulence, heartburn, regurgitation, insomnia, constipation and lack of appetite, of which many of these patients complained, disappeared in 73.4 per cent of the cases after appendectomies. In twelve persons more than 55 years of age, certain long-continued arthritic pains disappeared after the removal of the appendix. One hundred and thirty-seven patients complained of mild pains in the epigastric or the right hypochondriac region, which failed to localize at McBurney's (McArthur's) point; 214 complained of steady, dull, deeply situated pains in the right lumbar region of the back; eighty-eight experienced pains in the right shoulder and in 107 instances severe pains in the upper part of the abdomen continued for an average of 6.4 hours. Only 14

persons presented the fairly classic signs and symptoms of acute appendicitis and only two of this subgroup died of generalized peritonitis. The average oral temperature on admission was 100.4 F. Palpation presented a diffuse, mild, generalized tenderness in the right side of the abdomen located lateral and cephalad to McArthur's point. Hyperesthesia of the skin was rarely seen in the right lower quadrant of the abdomen. Muscular rigidity was absent in 397 instances. Rebound tenderness was absent in 243 cases. The sign most frequently obtained was the production of intense pain by exerting steady, deep pressure on the right flank lateral to the right psoas major muscle. Rectal examination in 218 instances gave the only positive signs of the existence of acute appendicitis. Correct preoperative diagnoses of acute appendicitis were made in only 554 cases, and only 304 were diagnosed as of the retrocecal variety. In seventy-seven patients walled-off retrocecal abscesses were palpated through exploratory midright rectus incisions. These were then closed without disturbing the abscesses and secondary muscle-splitting incisions were made directly over the abscesses and proper drainage was instituted. In the remaining 474 cases, in which either a midright rectus incision or a midline incision was employed, the appendix was removed usually through a lengthened incision with considerable difficulty. The average stay in the hospital for patients with an incision of this type was twenty-five days, as compared to sixteen days for those with a muscle-splitting incision. Localized abscesses were drained by the use of simple Penrose drains of soft rubber dam material. There were ninety-seven examples of secondarily formed pelvic abscesses that required drainage. Twelve of these patients died; ten deaths were attributable to nonmuscle-splitting incisions. Eleven instances of subdiaphragmatic abscesses were encountered and four of these patients died. There were eight patients with multiple abscesses of the liver, all of whom died. Of sixty-nine persons with postoperative pneumonia, nine died. Among the 113 instances of generalized peritonitis, there were twenty-five deaths. Only twelve of the fifty-eight deaths occurred in the cases in which muscle-splitting incisions were performed. Twenty-nine of the patients who died had taken one or more doses of laxative prior to hospitalization.

Intestinal Obstruction.—Sperling confines his study to increased intraenteric pressure as it occurs in simple ileal obstruction and the effects of such pressure on the structure, the function and the permeability of the intestinal wall. A detailed study is presented of the influence of simple mechanical ileus on the length, the weight, the water content, the blood content and the strength of the intestinal wall. Distention, with its increased intraenteric pressure, has a pernicious effect on the function of the intestine. It produces an alteration in normal physiology which is sufficient to explain many of the changes in cases of intestinal obstruction. With the onset of intestinal obstruction there is stasis of fluid and gas within the intestine. The stasis produces a slight increase of intraenteric pressure and a moderate degree of distention which stimulate the normal intestine to increased peristalsis. Distention and increased intraenteric pressure result in an augmented secretion of intestinal juices, which adds to the content of the intestine. Absorption is decreased early in the course of the obstruction. There is thus a progressive increase of distention and of intraenteric pressure. With a rise in intraenteric pressure there is eventually manifested interference with the circulation of blood to the wall of the intestine. Venous stasis ensues and causes infiltration of the intestinal layers with leukocytes. Eventually hemorrhagic infarction, necrosis and even perforation of the intestine may take place. If the intraenteric pressure is maintained over a sufficiently long time, the viability of the intestinal wall becomes impaired and its permeation by toxic material may take place through the gangrenous patches. Death is then due to peritonitis or to absorption of toxic material by way of the peritoneum.

Loss of Blood in Intestinal Strangulation.—From the results of 240 experimental strangulation obstructions Scott concludes that: 1. There is little or no evidence for the direct absorption of "toxic products" from strangulated loops of intestine. 2. There is little evidence for the transperitoneal absorption of "toxic products," except late in the course of strangulation obstruction, when the intestinal wall is no longer viable. 3.

Whole blood and plasma are apparently lost from the general circulation in quantities sufficient in themselves to account for the symptoms of shock and death which occur in most cases of strangulation obstruction.

Trichinosis in Montreal.—Gervais states that twice during 1935, in January and in November, the city health department was notified of the occurrence of cases of trichinosis in Montreal. In the first outbreak there were six cases and one death and in the second sixty-eight cases and no deaths. In neither epidemic was the source of the infestation found. The two outbreaks were unrelated. The second outbreak was limited to a group of people of German extraction who used various types of sausages which contained uncooked pork. Since many persons were known to have used the meat products from this establishment, the fact that only sixty-eight suffered from trichinosis indicates that only a small amount of trichina-infected pork had probably been used.

*Use of Chaulmoogra Oil in Treatment of Chronic Arthritis. D. W. Smith, Miami; T. G. Blocker and H. J. Tumen, Philadelphia.—p. 586.

Chaulmoogra Oil in Chronic Arthritis.—Smith and his associates believe that chaulmoogra oil (90 per cent chaulmoogra oil, 10 per cent olive oil and 0.2 per cent ethyl aminobenzoate) does give definite relief in chronic arthritis. Treatment of sixty-five patients was limited to the use of chaulmoogra oil. Foci of infection were not removed and no diet was prescribed. Treatment with chaulmoogra oil was postponed in the case of patients recently treated by other methods in order that results might be more definitely evaluated. In a few patients chaulmoogra oil was administered orally, either alone or in combination with the intramuscular treatment. The injections were given in the buttock, about 1½ to 2 inches below the crest of the ilium and above the border of the gluteus maximus. In this area a 3 or 4 inch needle is plunged, allowed to touch the ilium and then withdrawn one-fourth inch prior to the injection in order to avoid the subcutaneous tissues. The planned course of treatment consisted of eight intramuscular injections of chaulmoogra oil (5 cc. each) within six weeks; the first four biweekly and the others at weekly intervals. Of fifteen cases of atrophic arthritis, thirteen became symptom free. The two patients who were not rendered symptom free showed evidence of rheumatic heart disease. Eleven patients showed definite subjective improvement after the third injection. Objective joint changes were definite but more gradual. Eighteen of the thirty-three patients with mixed arthritis became symptom free and

fourteen showed moderate to marked improvement. The improvement corresponded roughly to the degree of atrophic or infectious involvement. In the seventeen patients having hypertrophic arthritis the results were entirely unsatisfactory. Eleven failed to improve at all. Five showed slight and one moderate improvement. Of the six patients who improved nearly all had a subsequent recurrence of symptoms. No objective changes were noted in any of the hypertrophic joints following treatment.

Leukopenic Index in Allergy.—Loveless and her associates state that experiments with the leukopenic index test on a group of nonsensitive subjects failed to support the contention that leukocytosis is the normal response to ingestion, since neither the level nor the fluctuation of the total leukocyte count during a seventy-minute postprandial period was significantly changed from the corresponding fasting period. A standard deviation of ± 511 leukocytes (equal to ± 7.3 per cent of 7,000 cells, the approximate average of all the counts) was found in six successive total leukocyte counts obtained on each of nineteen nonsensitive subjects. A fluctuation of 1,318 cells or more up or down from the mean total count would be expected to occur in analogous individuals, therefore, under the conditions of the test only once in a hundred trials by chance alone. About the same small proportion of normal subjects showed this degree of leukopenia after ingestion as did the food-sensitive patients after either compatible or incompatible food was ingested. In short, postprandial leukopenia was not found to be an index to incompatibility in the experiments. The development of asthma, hay fever and urticaria in a small group of ragweed-sensitive patients given ragweed extract subcutaneously was not associated with any significant change or fluctuation in the leukocyte level.

Lung Changes in Electric Arc Welders.—For the last three years Enzer and Sander have had under observation twenty-six electric welders of low carbon steel with rods of the same composition. In five of these, nodular shadows were seen on the roentgenograms of their chests which simulated a

modified type of silicosis. In five others the trunk shadows were markedly exaggerated, the appearance simulating a pre-nodular fibrosis of the type seen in older foundry welders. The past occupational histories were checked in detail for exposure to silica dust, but the majority had welded in this plant since they began work, an average total of nineteen years. These men were not breathing particulate matter to any appreciable degree other than that in the welding fume itself. Several of the sixteen men in whom there was no x-ray appearance of nodulation had worked as welders in this plant even longer than those who showed definite nodulation. Investigation revealed that each of the five men with nodulation had done more work inside of tanks than had the five showing only exaggerated trunk shadows but that the latter five had welded inside the tanks considerably more than had any of the sixteen men with perfectly clear lungs. Deposition of iron oxide in the lungs was responsible for the x-ray appearance of nodulation. Functional impairment of the lungs with such iron deposits appears to be lacking, both as to the development of clinical symptoms or susceptibility to complicating infections.

Health Hazards in Metal Spraying.—Miller and his colleagues studied the modern metal-spraying process under laboratory conditions which simulated industrial operations. No matter how careful or skilled the operator, it was found that some of the sprayed metal missed its mark and polluted the surrounding air. Lead, zinc, iron, brass, bronze, copper and aluminum wire were sprayed and the curves plotted show the rates at which the suspensions of the metals settled out of still air. The high muzzle velocity of the sprayed metal makes ventilation requirements for exhaust hoods unusually severe. It was found difficult to spray ordinary small objects, even when placed well back in the hood, without spray being blown back into the face of the operator. Freedom from the general pollution of the workshop was easily obtained when the spraying was done in a large booth or room which was well ventilated. Spray-gun operators should wear air-supplied respirators.

Nephrectomy for Hypertension.—Boyd and Lewis cite a case in which the true condition (arterial hypertension) was brought to light only after bilateral simultaneous exposure of the adrenals and kidneys followed by nephrectomy. The patient was relieved of his symptoms and his blood pressure returned to normal. The preoperative clinical studies placed the case in the category of malignant hypertension. If an infarct had not occurred nephrectomy probably would not have been done. The clinical result, to date, justifies the procedure. Experimental work on the subject of hypertension by Goldblatt seems to strengthen this view.

Effect of Sulfanilamide on Rheumatic Fever and Chorea.—Massell and Jones used sulfanilamide in the treatment of fifty-eight patients with rheumatic fever and seven patients with chorea. Sulfanilamide was administered in divided doses with a total daily dose of approximately from 6 to 7 grains (0.4 or 0.45 Gm.) per 10 pounds (4.5 Kg.) of body weight during the first twenty-four hours, and thereafter from 4 to 5 grains (0.26 to 0.32 Gm.). The duration of therapy varied from a few days to as long as two months. Of the fifty-eight patients given sulfanilamide, rash and fever developed in thirty-one. In no case did sulfanilamide produce any symptomatic relief or shorten the course of rheumatic fever. Likewise sulfanilamide therapy had no effect on the natural course of the chorea in any of the seven patients.

Calcification and Ossification of the Kidney.—Goldstein and Abeshouse state that in the human body calcification occurs either as a physiologic or pathologic process. Physiologic calcification is the normal process concerned with the deposition of calcium salts in the development and the formation of bone. Pathologic calcification includes the deposition or precipitation of calcium salts in those tissues or organs which ordinarily do not contain calcium deposits or concretions. For practical purposes they classify pathologic calcification into metastatic and nonmetastatic. In metastatic calcification the deposition of calcium salts presumably takes place in normal or uninjured

tissues, whereas the nonmetastatic type of calcification occurs in tissues or organs which are the site of localized changes predisposing to the deposition of the calcium salts. Nonmetastatic calcification may be further divided into dystrophic calcification, calcinosis, arterial calcification, stone formation and heterotopic ossification. The latter groups are briefly discussed only so far as they concern calcification of the kidney. Dystrophic calcification is the most common type of pathologic calcification encountered. Any dead or damaged tissue, infected or uninfected, so large or so situated that it cannot be absorbed, may become infiltrated with calcium salts. The location and distribution of these calcified lesions are extremely varied since every tissue and organ in the body is subject to retrogressive changes or lesions which predispose to the deposition of calcium salts. While this type of calcification is directly dependent on local retrogressive changes (fatty infiltration, hyalinization, necrosis and the like) which are the result of circulatory, toxic inflammatory or nutritional disturbances, the degree or extent of the calcification may be modified by general changes in calcium metabolism or in the amount of calcium in the blood or tissue fluids. The exact physicochemical changes involved in the deposition of calcium in the various types of pathologic calcification remain a matter of conjecture and controversy. The extremely variable degree of calcification observed in experimental and clinical conditions with hypercalcemia emphasized the difficulty of attempting to establish a predictable relationship between the degree of hypercalcemia and the deposit of calcium in the tissues. Any considerable increase in the concentration of serum phosphatase may disturb the equilibrium of calcium and cause a precipitation of calcium salts. Renal pathologic calcification is discussed and classified into three distinct types: 1. Metastatic calcification of the kidney (Kalkmetastasen) which occurs in those various bone diseases accompanied by a hypercalcemia. 2. Nonmetastatic calcification associated with a renal lesion which causes a decreased solubility of the calcium salts of the blood and tissue fluids or results in the faulty or impaired excretion of calcium salts from the kidney—the so-called Kalkgicht of Schmidt. 3. Nonmetastatic (dystrophic) calcification associated with a renal lesion in which the precipitation of calcium salts occurs in tissues presenting degenerative, vascular or retrogressive changes. In type 1, the essential factor is an increase in the calcium salts of the blood which is due to the absorption of these salts from the bone lesions. The majority of these cases develop in the absence of a renal lesion. In type 2, the important factor is a renal lesion which may be primary or secondary. Hypercalcemia is not essential to this type of calcification although the degree of renal calcification is more marked in those cases accompanied by a transitory or permanent increase in the blood calcium. In type 3, the essential factor is also a renal lesion which may be of an infectious, obstructive, traumatic or neoplastic character. Hypercalcemia does not play a primary part in this type of calcification.

Studies in Nail Growth. W. E. Le Gros Clark and L. H. D. Buxton. —p. 221.

*Pemphigus: Review of Seven Cases. J. Kinnear.—p. 236.

Pemphigus.—Kinnear reports seven cases of pemphigus: two in children, both of whom recovered; one case of pemphigus vulgaris and one case of pemphigus foliaceus, both of which were fatal; two cases of acute pemphigus ushered in by erythema multiforme in young girls, one of whom died and one recovered, and one in a patient presenting symptoms of dermatitis herpetiformis who recovered. The author's experience with a complex carbamide compound of trisulfonic acid (germanin) coincides with that generally recorded. Its action may be dramatic, satisfactory, useless or apparently dangerous. Its use may be followed by high temperature, renal symptoms and/or cutaneous eruptions; e. g., late erythema. However, it does deserve a trial. P-benzylaminobenzenesulfonamide was used in one case apparently with some benefit. Although the author treated only two patients locally the results make it evident to him that tannic acid and acriflavine jelly, as used for burns, are the treatment of choice for pemphigus since all the advantages of this treatment as used in burns were duplicated.

Estrogen Therapy.—Estrogen is now well established as a therapeutic agent, but many problems remain to be solved before the most effective mode of administration can be determined. Bishop describes the effect of estrogen on a castrated woman (ovariectomy for cysts). Administration of estrogen in quite small doses by mouth was effective in controlling symptoms of hot flashes. The level of theelin threshold bleeding was found to be between 6,000 and 5,000 international units by injection and between 25,000 and 30,000 international units by mouth, suggesting a peroral/intramuscular ratio of 5:1. A 14 mg. tablet of crystalline theelin was implanted subcutaneously and was effective in controlling symptoms for four or five weeks.

Insulin Resistance and Arteriovenous Blood Sugar.—Griffiths studied the effect of an intravenous injection of insulin on the rise in arterial blood sugar following the ingestion of dextrose in a number of normal and diabetic subjects. Some diabetic patients are sensitive to insulin, which either diminishes or abolishes the rise in arterial blood sugar as in the normal subject; others exhibit considerable resistance to the hormone

so that the arterial hyperglycemia is little affected. A study of the arteriovenous blood sugar difference revealed that in spite of the disparity in the effects of insulin on the arterial blood sugar in these patients there is no corresponding difference in the peripheral action of the hormone, which in both types is less than it is in the normal subject. For this reason it is concluded that although in all diabetic patients there is an enfeeblement of the peripheral action of insulin, resistance to insulin as determined by the insulin-dextrose test is mainly due to the inability of the hormone to exert its entire control over the storage of sugar in the liver. The frequent occurrence of negative arteriovenous differences (venous sugar exceeding arterial) in the diabetic patient and their rarity in the normal subject is discussed. As yet no completely satisfactory explanation of these negative differences is possible. It appears that the insulin-sensitive diabetic person is suffering from a lack of insulin and that the symptoms of the insulin-resistant patient are, at least in part, due to the activity of some factor which opposes the action of insulin on the storage of sugar in the liver. The possible relation between the relative inability of insulin to control hepatic glycogenolysis in the resistant patient and pituitary dysfunction are discussed.

Blood Circulation in the Human Limb.—Grant and Pearson show that differences exist between the circulation in the human extremities, apart from that of the hands and feet, and the circulation in the more proximal parts. In measuring change of cutaneous temperature and blood flow of the proximal parts precautions are required to exclude the effect of venous blood returning up the limb from the extremities. While in the extremities sensory stimuli applied to the body cause vasoconstriction, they have either no effect or cause vasodilatation in the forearm and leg. Small doses of epinephrine regularly cause an increase of the volume of the limb and an increased flow of blood in the forearm and leg due to vasodilatation in the voluntary muscles. The vasodilator reaction to epinephrine is increased after sympathectomy. In man, as in other animals, circulating epinephrine is not the factor responsible for the return of vascular tone following sympathectomy. The vascular changes in the distal and proximal parts of the limb are described in response to alterations of body temperature. Increased blood flow through active voluntary muscle exerts a conspicuous effect (by the conduction of heat) on the temperature of the overlying skin. Warming the body and muscular activity have a bearing on the maintenance of body temperature, both local and general. The arteriovenous anastomoses of the extremities play a greater part than was heretofore realized in maintaining the temperature of the limbs and in regulating body temperature.

Referred Pain Arising from Muscle.—Using the injection method Kellgren investigated the character and extent of the muscular pain provoked when solutions of sodium chloride were injected into muscles, tendons and the periosteum. He found that fascia and tendon sheath give sharply localized pain, while muscles give diffuse pain which is referred. The diffuse pain from a given muscle is always distributed within certain regions, though the distribution within these limits varies from person to person and according to the part of the muscle stimulated. Pain arising from the muscles may be confused with pain arising from other deep structures such as the joints and the testis. The distribution of the diffuse pain from muscles appears to follow a spinal segmental pattern. This pattern differs from that of the segmental innervation of the skin. Referred pain from muscles is associated with referred tenderness of the deep structures. It is suggested that the impulses responsible for pain from muscles and the other deep structures may follow a final common path in the central nervous system. Diffused pain might be explained by the pain fibers from muscles having diffuse instead of accurate central synaptic connections.

Nutrition and Disease of Nervous System.—Ungley presents evidence which justifies the belief that polyneuritis associated with alcoholism, pregnancy and gastrointestinal lesions is due, in some cases at least, to nutritional deficiency. Etiologic factors are low intake, poor assimilation and increased utilization of vitamin B₁. According to Strauss (1936), the neurologic manifestations do not differ from beriberi either clinically or pathologically. The cases described were characterized by sensory as well as by motor involvement, a fairly symmetric distribution affecting most of the distal parts of the extremities, with little or no increase of protein in the cerebrospinal fluid. There were mental symptoms in some instances. Low values for vitamin B₁ have been found in the blood in alcoholic polyneuritis and polyneuritis secondary to pyloric stenosis and a moderate value in polyneuritis of pregnancy undergoing spontaneous recovery. The excretion of vitamin B₁ in the urine was low in all cases and the response to test doses was slight or delayed. A response to vitamin B₁ therapy after a control period without improvement was observed in some cases, but the effects were not dramatic. Improvement was slow, owing perhaps to the time required for regeneration in severely damaged neurons. The possible role of deficiency of other food factors, particularly vitamin A, needs further consideration. Vitamin B₁ appeared to be without influence on other forms of polyneuritis. It is probable that subacute combined degeneration of the cord, like pernicious anemia, is the result of a nutritional deficiency based on a gastric defect. At present there is no conclusive evidence that any substance lacking the characteristic effect of liver on hemopoiesis in pernicious anemia can arrest the progress or influence the course of subacute combined degeneration of the cord. Most cases of subacute combined degeneration of the cord could be prevented by early recognition, accurate diagnosis and efficient treatment of pernicious anemia. With adequate liver treatment, preferably parenteral, the nervous lesions can be arrested. No case of subacute combined degeneration of the cord, however severe, should be abandoned without recourse to intensive parenteral liver therapy.

Action of Testosterone Propionate in Women.—The outcome of animal experiments with testosterone propionate has led to its use as a remedy for excessive and irregular uterine bleeding due to hyperfolliculinemia in women, especially as Zuckerman's work was fairly conclusive that it caused no undesirable secondary effects, except perhaps enlargement of the clitoris. Foss used testosterone propionate in sixteen cases and found that for most patients total doses of from 300 to 800 mg. are required, according to the severity and duration of bleeding and the nature of the disorder to inhibit endometrial proliferation. In some cases of menorrhagia cyclic doses of from 20 to 40 mg. given twice a week for a few months are sufficient to counteract follicular overaction or to restore a cyclic rhythm in metrorrhagia. In severe cases a total dose is required of from 800 to 2,000 mg. given in daily injections of 100 mg. or injections given twice a week of from 150 to 200 mg., the individual dosage being adjusted to the clinical history. Metrorrhagia and menorrhagia can as a rule be controlled by injection of testosterone propionate in adequate doses. Two patients have proved refractory to treatment, even with large doses of testosterone propionate. No harmful effect, however, has been noticed in the sixteen patients.

Complications During Gold Therapy.—According to Secher, the reactions provoked by double sodium gold thio-

sulfate therapy in tuberculosis and arthritis are attributed to liberation of toxins from tuberculous or rheumatic lesions. They may be prevented or checked by giving large doses of vitamins A, B and C before and during treatment.

Desensitization in Treatment of Tuberculous Guinea Pigs. J. D. Thayer.—p. 365.

Tuberculin.—Parish discusses the preparation and purification of tuberculin, the stability of dilutions of tuberculin, the reactions in the laboratory following inhalation of tuberculin, the standardization of tuberculin and tuberculin in diagnosis, treatment, prophylaxis and veterinary practice. The term tuberculin as he uses it includes all preparations which have a specific irritant effect on the sensitized cells of man or animals infected with tuberculosis. The specific active principle, called purified protein derivative, is of protein nature and is the best reagent so far produced for diagnostic tests in man. Its preparation and obvious advantages over old tuberculin are discussed. The possibility of acute general tuberculin reactions of varying severity among laboratory workers has frequently been recognized. The symptoms arise from the inhalation of either dry preparations or of minute particles of liquid tuberculin dispersed by centrifugation, bubbling when tuberculin is being "stewed down" or other manipulation. Headache, dyspnea, a tight feeling across the chest, perspiration and slight pyrexia have been observed, entailing absence from work for two or three days. Lassitude persisted for a week or longer. In the past, it is possible that the association with tuberculin may have been unrecognized by some bacteriologists, who may have diagnosed the symptoms as influenza or asthma. The Mantoux test should replace all others in the diagnosis of tuberculous infection, for it permits accurate and graduated dosage. In connection with these tests, the extraordinary property possessed by tuberculin of adhering to glassware must not be overlooked. Tuberculin plays an increasingly important part in the diagnosis and prognosis of tuberculosis in man and is also invaluable in epidemiologic studies. Treatment with tuberculin, which is little used at present, might possibly be resumed under carefully controlled conditions. In veterinary practice, the intradermal test with potent tuberculin is highly specific in cattle and is a reliable indication of the presence of infection. It is being used increasingly to build up tuberculosis-free herds in England. While no claims have been made in recent years for the protective value of old tuberculin, prominence has been given to two suspensions of tubercle bacilli; namely, BCG and Spahlinger vaccine. The activity of these preparations probably does not depend on their tuberculin content. The role of BCG vaccine in the prevention of tuberculosis has not yet been fully established. Any immunity induced by the method appears to be incomplete and of short duration. It is believed by many workers that BCG is a more efficient antigen than dead tubercle bacilli, although the latter will produce tuberculin allergy and confer sufficient protection on guinea pigs to justify further clinical trial. The object in using Spahlinger vaccine is to reproduce natural conditions of growth. No heat or chemical is used to kill the bacilli, which are allowed to die naturally in one year or more (Spahlinger, 1932). Full details of the method of preparation have not yet been divulged. While the results indicate that the vaccine may have some protective effect, further investigations are required in the laboratory and elsewhere.

Annales de Médecine, Paris

 Treatment of Catarrhal Icterus by Chologogues. E. Chabrol.—p. 398.

Intolerance and Catarrhal Icterus.—Caroli points out that intoxication, often of alimentary origin, is the cause of a number of cases of benign icterogenic hepatitis. He reviews a case the anaphylactic origin of which appears certain, since it developed in connection with a serotherapeutic accident. An injection of antitetanus serum was followed by severe headaches. From the twelfth day on, the urine contained biliary pigment; all possible care could not prevent the appearance of jaundice, but for three more days the icterus remained latent, while the migraine persisted with almost intolerable severity. When on the fifteenth day the signs of biliary retention became manifest, the severe headaches disappeared. Following a discussion of the macroscopic aspects of the liver, the histologic aspects of the sections, the chemical analysis of the bile and the results of the intervention, the author emphasizes that this case demonstrates that an edema of anaphylactic origin may be the cause of an icterogenic hepatitis. He says that this is by no means the first observation that a catarrhal icterus has been preceded by signs of intolerance, particularly by urticaria. In an earlier report he pointed out that preicteric rheumatism, by its frequent association with urticarial eruptions, constitutes together with them a prodromal complex of spontaneous serum disease. Urticaria may assume the aspects of Quincke's edema. On the other hand, certain cutaneous eruptions have a similar semeiologic value. Dyspeptic disorders are often entirely absent; it is as if the cutaneous disorders served as their equivalents. The author further directs attention to the antagonism between the urticarial symptoms and the icterus, for the cutaneous manifestations cease instantly on appearance of the signs of biliary retention. Arthralgias are often associated with urticaria or Quincke's edema. The author points out that the violent preicteric headaches may be of anaphylactic origin and an equivalent of urticaria and arthralgia. The author further cites from the literature instances revealing the role of intolerance in icterus. He mentions the icterus that develops in connection with anti-syphilitic therapy, with the use of chloroform, with alimentary intoxication and so on.

 *Studies on Vitamin C Metabolism: Physiologic Aspects of Metabolism During Spontaneous Conditions and After Saturation. M. Vauthey.—p. 351.
 Glycosuria and Diabetes with Cancer of Pancreas.—J.-V. Grott.—p. 361.

Metabolism of Vitamin C.—In this paper Vauthey reports further studies on the vitamin C metabolism (see also *Archives des maladies de l'appareil digestif* 28:230 [March] 1938; abstracted in *THE JOURNAL* of June 4, 1938, page 1963). He shows that the comparison of the results of the various tests are highly instructive, particularly the differences in the values that are obtained in an organism moderately charged with vitamin C and in one artificially charged with vitamin C. He studied the fasting ascorburia first in the course of the normal metabolism and then after saturation; that is, after the person had been given daily for ten days 100 mg. of ascorbic acid. He found that the saturation doubled the fasting ascorburia. Then he studied the basic ascorburia after progressive saturation. Whereas the five day average of basic ascorburia is 0.94 under ordinary conditions, it rises to 1.39 in the course of five days of progressive saturation and to 1.60 at the end of another five days of progressive saturation. The third group of tests carried out by the author were those concerning the twenty-four hour excretion, first under normal conditions, then after ten days of progressive saturation and finally after massive saturation. He considers the twenty-four hour excretion after the massive saturation as the most important and the most

interesting test. In making the latter examination he used a modification of Youman's test, in which 600 mg. of ascorbic acid is given. This test, for which he found in the normal state a numerical value (from 28 to 29 per cent of the ingested dose) exactly intermediate between that of American (30 per cent) and English authors (27 per cent), seems to give for a normally charged organism a constant and relatively fixed result. The test is of great value; in the clinic its total results make it possible to determine in a given case whether the organism is charged with or has a deficiency of vitamin C; by its fractionated results of the first hours it indicates the quality and intensity of the digestive resorption of the administered vitamin C.

 *Epidemiologic Aspects of Epidemic Encephalitis in Japan. R. Inada.—p. 851.
 Vascular Spasm Provoked "in Vitro"; Experimental Study with Aid of Isolated and Surviving Vascular Piece. A. Mougeot.—p. 853.

Epidemic Encephalitis in Japan.—Inada surveys epidemic encephalitis in Japan during the years from 1924 to 1935 inclusive. He shows that in some regions of Japan, particularly in those bordering on the sea of Japan, epidemic encephalitis is frequent and exists almost constantly, whereas in other regions epidemics occur interruptedly, and in still other regions epidemic encephalitis occurs only sporadically. The number of cases of epidemic encephalitis occurring annually during the years from 1924 to 1935 are listed in a table. This tabular report indicates that the epidemic of 1924 was the most severe; then follow in the order of their severity the epidemics of 1935 and 1929. The more severe epidemics seem to recur at intervals of five or six years. In other tables the author lists the monthly incidence of the cases of epidemic encephalitis. These tables indicate that the morbidity culminates during August and September. The author thinks that a maximal morbidity during the summer months constitutes one of the characteristics of the Japanese type of epidemic encephalitis. Discussing the incidence of epidemic encephalitis in the two sexes, the author shows that the morbidity is greater in men than in women (124 to 100). Further he shows tables indicating the incidence of epidemic encephalitis in different age groups during the various epidemics as well as the mortality rate for the different age groups. The tables indicate that the mortality is greatest in the higher age groups. The author says that reinfections are extremely rare. Discussing individual predisposition he says that nervousness, neurasthenia and other disorders of the nervous system seem to reduce the organism's resistance to epidemic encephalitis. Overexertion, mental as well as physical, and exposure to the hot sun seem to be predisposing factors. The author cites other climatologic factors that seem to be of significance in the development of epidemic encephalitis.

 Treatment of Diabetes Mellitus in Children by Free Diet. A. W. Vetter.—p. 662.

Familial Icterus of the Newborn.—In this extensive report Péhu and his associates discuss Pfannenstiel's type of grave familial icterus of the newborn. Their report covers seventy familial series, sixty-five of which they collected from the recent literature and five of which they observed themselves. After calling attention to the growing interest in this disorder during recent years, they define the subject, give a historical review, cite cases from the literature and then describe their own observations. They point out that grave familial icterus can no longer be regarded as a rare disorder. In recent years the cases of grave familial icterus in the newborn seem to have multiplied and the authors think that this is due to the fact that attention has been called to this disorder and that obstetricians

and pediatricians think of this type of icterus and are able to recognize it clinically and hematologically. A study of the pathologic antecedents of the parents of families with grave icterus of the newborn reveals some interesting factors. It has been observed that in families with this form of icterus the first or the first two or three infants are free from the icterus. While this rule is not absolute, it is nevertheless observed in the majority of cases and it is a phenomenon that is difficult to explain. The obstetric antecedents are often quite interesting. A review of a number of familial series reveals not only deaths from grave icterus, that is mortality of the newborn, but also an increased number of abortions, premature deliveries and stillbirths. This has been known for a long time, but it is only since von Gierke demonstrated the pathologic identity of fetoplacental dropsy, of grave icterus (type Pfannenstiel) and of the anemia of the newborn that more attention has been given to this polymortality. After citing a number of familial histories illustrating this polymortality, the authors discuss the aspects of the blood in grave familial icterus of the newborn. It appears well established that in the majority of cases an erythroblastemia exists, but this anomaly is not constant. In some authentic cases it is missing. The authors enumerate the cases of grave icterus without erythroblastosis but show that in some of these cases the examination was not sufficiently detailed. They emphasize that in grave familial icterus of the newborn it is indispensable that the blood be examined from the first hours after birth and that it be repeated several days in succession for a week. After directing attention to the desirability of the examination of the bone marrow in cases of grave familial icterus, the authors discuss the prophylaxis and treatment. They admit that in view of the uncertainty about the pathogenesis and the pathologic physiology there is as yet no truly rational treatment. Nevertheless, it has been recommended that hepatic preparations be administered during the last three months of gestation. The authors think that this is too late and that the treatment be instituted when the intrahepatic erythropoiesis begins in the embryo; that is, about the fourth month. In order to avoid the development of a state of intolerance toward the medication it may be discontinued from the end of the fourth to the beginning of the seventh month. The use of vitamin C during pregnancy has also been suggested. After birth, the blood of the child must be kept under careful observation and if necessary blood transfusion should be resorted to. In the final chapter the authors cite several problems that still await solution.

Pressure of Cerebrospinal Fluid in Cerebral Traumatism.—Decker discusses the possible causes of the increase in intracranial tension after cerebral traumatism and the treatments that aim at the dehydration of the brain. He points out that this method is not without danger for, if continued too long, it may give rise to the phenomenon that is referred to as toxic dehydration. Consequently, it is important to know when to suspend the dehydration. The author found that his determination of the differential pressure of the cerebrospinal fluid is of value in this respect. He measures the pressure of the cerebrospinal fluid at the beginning and at the end of lumbar puncture during which a definite amount (perhaps 1 cc. of fluid) is extracted. In one case of commotio cerebri, the pressure at the beginning of the lumbar puncture was 22 cm., after the extraction of 1 cc. of fluid it was 17 cm., and after the extraction of 2 cc. it was 13 cm. Thus the differential pressure per cubic centimeter was 4.5 cm. Repeated lumbar punctures

revealed that this differential pressure subsided gradually. The author gained the impression that the differential pressure during a number of cases of cerebral traumatism seems to be related to the variations in the cerebral volume, which are the result of the edema. He thinks that the study of the differential cerebrospinal pressure can aid in directing the treatment of the post-traumatic cerebral disturbances, particularly if the treatment consists in dehydration.

Massage in Phlebitis.—Henschen and Becker say that massage in phlebitis can mobilize a latent infection or even elicit an embolism. However, the authors recommend massage only after the phlebitis or thrombophlebitis has subsided. The signs of inflammation must have subsided. The vein in question must no longer be sensitive to pressure. In case of deeper processes on the leg, the pressure points medial to the tibia must be tested. Moreover, all the manipulations for the detection of a latent phlebitis should be used. To detect a subfascial inflammation, pronation of the foot, or adduction, hyperextension or exterior rotation in the hip joint for the purpose of eliciting pain have been recommended. Moreover, subjective pains in the muscles and nocturnal muscular spasms must have subsided. Body temperature and pulse rate must have returned to normal. The sedimentation speed must either have become normal again or be on the decline. Moreover, the authors also used the Aldrich-MacClure test. In case of an accelerated resorption of the wheal, they regarded massage as too early. If the various tests and examinations disclose that the phlebitic process has subsided, the authors begin the massage with a mild effleurage. It serves to detect possible painfulness and changes in the pulse frequency and discloses whether real massage of the veins and the surrounding tissues can begin. In view of the purpose for which it is employed, massage consists chiefly in stroking and rubbing manipulations. The authors mention first the longitudinal massage of the saphenous veins, consisting in a loosening of the tissues surrounding the veins and in a light massage of the venous walls. Then there is the oblique massage of the branches of the veins, which influences the tissues surrounding the veins, and then the veins themselves. There is rolling massage and finally indirect elongation massage by means of alternating flexion and extension of the leg. In evaluating venous massage, the authors stress that it promotes the metabolic processes of the venous wall by way of improving the circulation of the vasa vasorum; that it softens the venous wall, exerts an antispasmodic action, accelerates the blood stream, improves the function of the venous valves and has an indirect effect on the joints which may be involved in the phlebitic process and so on.

Experiences with Catgut.—Ritter cites a number of still unsolved questions that arise in connection with the use of catgut in surgery. In order to clarify these problems, a questionnaire was submitted to a number of Swiss surgeons and the author summarizes the answers. He found that in spite of many theoretic objections to the use of catgut, and the partial inadequacy of the chemical methods of sterilization, catgut is used extensively as suture and ligature material. Various amounts of iodine or other chemicals are contained in the different types of catgut, but there is little difference in sterility. The forms of catgut which are marketed ready for use are practically sterile. In the cases in which catgut was suspected as being the source of an infection this could not be proved. Since the sterility of the catgut of thin caliber is more reliable than that of the thicker threads, the author thinks that whenever possible the thin catgut should be used; if necessary, it could be doubled. Sterilization of catgut in the general routine of the operating room is probably too complicated and not always feasible. A substitute for catgut, a resorbable preparation made from muscles of horses, has not proved entirely satisfactory; nevertheless the author thinks that science, technic and industry should make all efforts to develop a satisfactory substitute. In order to increase the tensile and knotting strength and to prolong the time of resorption, catgut has been impregnated with metals such as chromium, gold, silver, copper and mercury. Experiences with the catguts impregnated with gold or chromium have been favorable, but these preparations do not have distinct advantages over iodized catgut. The reports of Swiss

surgeons differ from reports in the foreign, particularly French, English and American literature, as regards disturbances of the healing process caused by transmission of bacteria from nonsterile catgut; in this respect, the Swiss reports are negative. The Swiss, like others, complain of irritations due to reactions to the introduction of the foreign body and its chemical contents. However, in contradistinction to the foreign reports the Swiss surgeons did not observe allergic reactions to catgut.

Stomach and Pancreas in Heart Diseases.—According to Bologna and Costadoni, the development of gastric disorders and gastralgia is frequent in diseases of the heart. The authors followed the behavior of the gastric and pancreatic functions in sixty patients ranging in age from 16 to 81 years who were suffering from heart disease. They found that gastralgia is rare and unrelated to the circulatory insufficiency. It is due to atheromatosis of the abdominal aorta and its visceral branches. More rarely it is due to intermittent claudication of the stomach or to acute or chronic coronary atherosclerosis. Insufficient digestion is in direct relation to decompensation and the seriousness of circulatory insufficiency and venous stasis of the gastric wall. Generally the cardiac disturbances overshadow the gastric disorders, although in some cases the reverse is true. The diagnosis of insufficient digestion is easily made. The therapeutic test is of value in doubtful cases. Digestive disorders of cardiac origin are controlled by administration of cardio-kinetic drugs rather than by digestive substances. In grave decompensation with peripheral edema there is stasis of the gastric juice during fasting. The total and free hydrochloric acid are low or there is anacidity. The gastric secretion contains a large amount of mucus. The gastric secretion is normal, however, in some cases of mild decompensation. External and internal functions of the pancreas are normal in compensation and diminished in decompensation. The author concludes that decompensation induces diminished function of the digestive tract and the pancreas. The venous stasis from decompensation causes anatomic injury of the stomach, intestine and pancreas, which may be permanent if stasis is grave or repeated.

Erythrocyte Sedimentation in Pretuberculosis of Children.—Vanni followed the behavior of the sedimentation speed of erythrocytes in the blood of eighty-five normal children and of forty-one who were suffering from either tuberculosis or a pretuberculous or nontuberculous disease. The determinations were made after the first hour in the Westergren test. The author concludes that the speed of the erythrocyte sedimentation in normal children aged from 1½ to 14 years varies from 14 to 8 mm. Figures from 14 to 16 mm. are normal, especially in children under 4 years of age. The average difference between samples of blood taken during a period of fasting and of digestion, respectively, or at different intervals during the day is about 2 mm. The average difference in two tests made simultaneously on the same sample of blood is about 1 mm. Variations of only a few millimeters in the results of a test in

comparison with normal figures or with those obtained in previous or following tests have no significance as to results. There are certain slight increasing or diminishing collective periodic variations in the results of the test of sedimentation of the erythrocytes that are of unknown cause; they may last for five or six days and then disappear. The sedimentation speed of erythrocytes is normal in children who have pretuberculosis and adenopathies and give a positive reaction to tuberculin. It is increased in grave forms of tuberculosis and in tuberculous and benign lymphocytic meningitis, as well as in malignant lymphogranuloma. It is slightly increased in subacute diseases of the respiratory tract and in erythema nodosum.

Treatment of Fat Embolism.—According to Rappert, there were sixty-nine severe cases of fat embolism observed at the Second Surgical University Clinic in Vienna between Jan. 1, 1933, and May 1, 1937. A differentiation is made between fat embolism of the lesser circulation alone and that of the lesser and greater circulation. Fat embolism of the greater circulation alone is theoretically possible in the presence of patent foramen ovale. Clinically, however, it has never been observed. The symptoms of fat embolism of the lesser circulation are dyspnea, cyanosis, small, fast, almost imperceptible pulse, pale, waxy-yellow skin and restlessness. The symptoms of fat embolism of the greater circulation are disturbances of consciousness, convulsions, paralyses, rise of temperature, oliguria and anuria. Secondary anemia, shock and multiple rib fractures are to be considered in the differential diagnosis. Both surgical and medical therapeutic measures so far proposed for this condition were without result. The therapeutic problem, according to the author, consists in reducing the large droplets of fat which obstruct the capillaries to smaller droplets in order to enable them to pass through the pulmonary filter. The well known fat solvents and emulsifiers failed to accomplish this in animal experiments. With the use of decholin (sodium salt of dehydrocholic acid) in combination with circulatory stimulants and a papaverine preparation the author was able to save experimental animals after injecting into them several times the fatal dose of fat. On the basis of his animal experiments and the use of sodium dehydrocholate in severe clinical cases of fat embolism the author developed the following scheme of treatment: The patient must be kept at absolute rest and, if necessary, given opiates. A drip transfusion is instituted and sodium dehydrocholate is administered in large doses (from 200 to 300 cc. of a 20 per cent solution daily). The effect of sodium dehydrocholate is prompt and is manifested in quiet, deep respiration, the disappearance of cyanosis and an improved pulse. The effect of the sodium dehydrocholate can be enhanced by the exhibition of a 25 per cent solution of pyridine betacarboxylic acid diethylamine, metrazol and other drugs. The effect of sodium dehydrocholate can be further improved by administration of a papaverine preparation, which has the effect of dilating pulmonary capillaries. Renal complications such as oliguria and anuria were treated with sodium dehydrocholate, caffeine, a papaverine preparation, theophylline with ethylenediamine and prolonged diathermy of the kidney. The treatment of fractures is undertaken several days after the disappearance of symptoms of fat embolism and even then in a careful manner. The injection of large doses of sodium dehydrocholate is apparently harmless. It produces icterus, which however does not last more than twenty-four or forty-eight hours. The author stresses the advisability of repeated massive blood transfusions to combat anemia. Of the forty-nine patients not subjected to this treatment, only one survived (2 per cent); of the twenty patients treated with sodium dehydrocholate, seven (35 per cent) have survived.

*Making Roentgenograms of Heart During Certain Phases of Its Action. H. Ludwig.—p. 515.

Roentgenograms of Heart.—Ludwig stresses that roentgenograms which are made to determine the size of the heart must be made during a certain phase of the cardiac action. Studies on fluctuations in the size of the heart are reliable only if they are based on exposures that are made always during the same phase of the cardiac action. The author describes and illustrates a simple apparatus which makes possible the elicitation of an exposure during a definite phase of the heart action. Exposures that were taken with the aid of this apparatus revealed that the differences between the maximum and minimum of the transverse diameter of the heart may be considerable under identical conditions, that is, caused only by the action of the heart. These differences are in most cases in excess of 5 mm.

Smoking in Internal Diseases.—Schmidt says that the effect of tobacco smoking is not identical with the action of the alkaloid nicotine but involves a number of other factors as well. For this reason he avoided the term nicotine poisoning. It cannot be denied that there are persons who smoke much and still feel well and reach an advanced age although it would be illogical to conclude from this that smoking is entirely harmless. In considering the effects of smoking it is necessary to pay attention not only to the process of smoking but also to the condition of the smoker. In some persons the moderate use of tobacco may be not only permissible but even desirable. In this connection the author mentions Bezcny's observation that in some cases of chronically relapsing apthae smoking has been known to have beneficial effects. Nevertheless, since immunity to the ill effects of nicotine is difficult to determine and since the harmful effects are rather frequent and severe, a general campaign against smoking is justified. After pointing out that smoking may have a sedative as well as a stimulating action, the author takes up the sensitization that may result from the use of nicotine and mentions other factors that play a part in this nonspecific sensitization, such as congenital weakness of some organs, endocrine disorders, latent infections, metabolic anomalies, exogenic intoxications and excessive exertion. In the so-called erethistic asthenic types these factors are most likely to exert their full effect. Moreover, these persons seem to crave stimulants as well as sedatives more than do others and thus a vicious circle is set up. The author further discusses the disorders caused by nicotine in the digestive tract, circulatory apparatus, nervous system, endocrine glands and respiratory tract. Discussing the factors that increase the harmful effects of tobacco, he mentions the smoking of the last third of the cigaret or cigar (increased nicotine content), the smoking of fresh and moist cigars, the smoking of tobacco that has only been dried and has not undergone fermentation, the inhalation of smoke and smoking on an empty stomach. With regard to the breaking of the nicotine habit, the author says that complete abstinence is better than mere reduction in quantity, for the smoking of one cigar or cigaret readily leads to another one. The demand for abstinence is the more urgent, the more serious the disorder (angina, sclerotic hypertension, intermittent claudication) and the more certain it is that the nicotine plays an important part in the pathogenesis of the process. In case of sudden withdrawal there may be a tem-

porary increase in nervousness and congestions but there are never threatening symptoms. Measures that may be helpful during the beginning of the period of abstinence are chewing of gum or of lozenges or irrigations with 0.1 per cent solution of silver nitrate. If possible, the time of complete withdrawal should be arranged so that it concurs with the beginning of a vacation.

*Renal Tuberculosis. P. Clairmont and F. Schaffhauser.—p. 1115.

Renal Tuberculosis.—According to Clairmont and Schaffhauser, every case of tuberculosis calls for examination of the genito-urinary tract. The finding of tubercle bacilli in the urine demands a cystoscopic examination, determination of renal function and ureterocatheterization, in order to demonstrate the localization of the lesion. One hundred and fifty-three patients admitted to their clinic (Zurich) were treated by practicing physicians for chronic cystitis for a period of not less than three months; seventy-nine of these cases were not properly diagnosed and sixty were considered cystitis. Conservative treatment in cases of renal tuberculosis leads to the extension of the disease to the kidneys, the bladder and the genitalia. Such patients are a source of danger to their community because of the excretion of tubercle bacilli in their urine. The authors feel that primary tuberculosis of the renal pelvis probably does not exist. Temporary encapsulation of a tuberculous focus in the kidney is relatively rare. As a rule the tuberculous lesion progresses to involve more renal tissue with caseation, cavity formation and extensive destruction of the organ. Complete isolation of a tuberculous focus from the excretory urinary passages by scars is possible. They emphasize the frequent occurrence of severe toxic nephritis in the nontuberculous kidney which may disappear after the removal of the tuberculous kidney, although in many cases it may be the cause of fatal uremia. Spontaneous cure of chronic caseating renal tuberculosis has been reported only twice, once by Castaigne and once by Wildbolz. The authors quote the work carried out in their own clinic by Dimitza and Schaffhauser, in which 225 patients with extrarenal tuberculosis were studied by the method of animal tests and culture of tubercle bacilli. Of the thirteen patients in whom tubercle bacilli were demonstrated in the kidney urine, necropsy showed eleven to have renal tuberculosis. The important question from a therapeutic standpoint is whether the clinical diagnosis of an early caseous renal tuberculosis, based on the demonstration of the bacilli, the pyuria and the diminished function, constitutes per se an indication for nephrectomy. The question of bilateral involvement in the early cases is a difficult one. The indication for nephrectomy in unilateral early tuberculosis is established when repeated examinations over a fairly long period of time demonstrate that the other kidney is not tuberculous and that the involved kidney shows signs of progression of the disease, a considerable pyuria and a diminished function. Conservative treatment is not justified because one cannot expect a spontaneous healing of even a small caseating focus. The earliest symptoms are frequently those of cystitis. In about 17 per cent of the cases a typical renal colic may be the first manifestation. Every case of renal colic without a demonstrable stone should arouse suspicion of tuberculosis. In about 5 per cent the first symptom is hematuria, which is, as a rule, painless. The cardinal symptom of renal tuberculosis is the demonstration of tubercle bacilli in the urine. Patients with unilateral renal tuberculosis treated conservatively die, as a rule, in the course of five or six years. As contrasted to this high mortality the authors quote almost 80 per cent of permanent cures following early nephrectomy, and from 50 to 60 per cent for the late cases. The authors therefore stress the early diagnosis and the earliest possible nephrectomy in unilateral renal tuberculosis.

Vitamin B₁ Content of Certain Indian Foodstuffs. W. F. Donath and J. P. Spruyt.—p. 915.

Further Studies on Xerophthalmia. G. A. Hadikoeseomo.—p. 935.

Etiology of Tropical Sprue.—Hopman, after pointing out that various theories have been advanced about the cause of tropical sprue (infection, vitamin deficiency and so on), discusses the metabolic conditions under different latitudes but particularly in the tropics. If a person from the northern latitudes comes to the tropics, his energy consumption and blood pressure are decreased, as is also the production of the digestive juices; in fact the entire metabolism is at a lower level and it becomes necessary to reduce the intake of food, particularly foods with high caloric value such as fats. If carbohydrates and fats are taken in too large quantities for the prevailing metabolic conditions or if the organism utilizes inadequate amounts, various disorders may result. In this connection the author discusses the etiology of such disorders as obesity, diabetes mellitus and sprue. Obesity develops when fats and carbohydrates are absorbed by the organism but are not entirely utilized for energy production and become deposited under the skin or in the organs. Glycosuria develops when the carbohydrates are no longer all absorbed by the organism but are eliminated with the urine. Sprue seems to be connected with an excess of fats; after a hyperfunctioning of the liver and pancreas there develops a dysfunction of both organs, particularly the liver; the bile acids are secreted in inadequate quantities and thus the fats are not properly absorbed and large quantities of fatty acids and of cleavage products of fat are found in the stools. Under the influence of the inadequate utilization, abnormal processes of fermentation, borborygmus and meteorism develop and it is probable that toxins are formed. As the result of the poor utilization of the fat, swellings of the mucosa develop. Secondarily there is an impairment in the absorption of other foodstuffs. Vitamin B deficiency anemia and emaciation develop. The fact that sprue is more frequent in adults and in sedentary workers than in children and in persons who do physical work the author traces to the greater energy requirements of children and of physical workers. The morning diarrhea in sprue he ascribes to the fact that during the night the energy metabolism is at a minimum so that many unutilized fats are eliminated. The failure of liver therapy in sprue is due, he thinks, to the fact that it counteracts a symptom rather than the cause of the disease. The author reaches the conclusion that obesity, diabetes mellitus and sprue are safety valves which protect the organism against overheating if excessive amounts of calories are taken in. Moderate intake of food and sufficient exercise are helpful in the treatment and prevention.

Lobectomy and Pneumectomy for Bronchiectasis and Bronchial Stenosis. J. Holst.—p. 87.

Intussusception.—Björkroth states that among twenty-one patients treated at the Norrköping Hospital for intussusception between 1900 and 1937 there were fifteen cases due to functional invagination, three caused by a tumor, and three cases caused by Meckel's diverticulum. He stresses the diagnostic as well as the therapeutic value of the opaque enema. It was administered in seven recent cases, in six of which typical

pictures of intussusception were obtained. The treatment in the first group was operative. Reduction was possible in eight, resection was necessary in two and there was a spontaneous reduction disclosed at operation in one. An attempt to reduce the intussusception by opaque enema and manipulation was tried in two but was only partially successful and was therefore followed by operation. Because little contrast material can be made to pass the ileocecal valve, manipulation can give little information as to the completeness of the reduction, nor can it have any effect on an intussusception situated at a higher level. The better results obtained in recent years both by manipulative and by surgical means are due to earlier diagnosis. The partial disinvagination brought about by an opaque enema makes the subsequent surgical correction easier. In the four cases of invagination caused by tumor, three were adenomas of the small intestine and one a lipoma. There is possibly no difference between polyposis of the small and the large intestine. The lesser tendency to malignant degeneration on the part of the polyps of the small intestine is probably due to the fact that they are exposed to less irritation than those of the colon and that they are detected early because they give rise to complications at an early stage.

Electrocardiographic Examinations of Operative Patients.—Brodersen states that preoperative cardiographic studies on patients past 50 years of age disclosed abnormalities in forty-eight of 100. In the group of fifty-two patients with normal electrocardiograms there occurred eight postoperative fatalities, which, however, were not due to cardiac complications. There were likewise eight postoperative fatalities in the group of forty-eight patients exhibiting abnormalities in the electrocardiograms, but in only one of these was the death caused by the heart condition (coronary infarct). Temporary postoperative fibrillations occurred in two cases in which the electrocardiogram had previously been found normal. There occurred no cardiac complications, apart from the one fatal case, among the forty-eight patients whose electrocardiograms exhibited deviations from the normal. No patient in the group was denied operation because of the electrocardiographic observations. The author concludes that electrocardiographic irregularities cannot be accepted unreservedly as a contraindication to operative intervention. The doubtful alterations may be disregarded altogether, while the definite alterations must be considered individually. The history and the clinical symptoms are to be considered of greater importance than the evidence furnished by the electrocardiogram. Major operative interventions may be safely carried out in patients with positive electrocardiograms but with compensated hearts.

Hemangioma of Interosseus Muscles.—A woman aged 47 had had a swelling of the dorsal side of the right hand for a year, without preceding trauma, which increased somewhat and caused tenderness and pain. Sprensen reports that external examination together with roentgen examination pointed to a lipoma (pseudofluctuation, rhabdomyoma or sarcoma). Operation revealed a cavernous hemangioma in the interosseus muscles which had developed partly by growing through and partly by pushing aside the surrounding tissue, and because of its localization to the interstice the cavernoma had caused deviation and atrophy of the adjacent metacarpal bones. The case is unique because of the changes in the bones. The tumor contained fully developed bone tissue, which supports the theory of an embryonal disturbance as the cause. Complete removal of the tumor resulted in recovery.

CLINICAL RESEARCH IN PRIVATE PRACTICE

WINGATE M. JOHNSON, M.D.
WINSTON-SALEM, N. C.

"Let your light so shine before men, that they may see your good works" (Matthew 5:16).

A recent book by Stuart Chase has a most fascinating title—"The Tyranny of Words." The very name is enough to stimulate endless reflection as to how almost everybody, no matter how intelligent, is influenced, if not dominated, by the meaning attached to certain words or phrases. How contradictory may be one's reactions to different terms with virtually the same meanings! For example, it makes all the difference whether a woman is called "slender" or "skinny," "fat" or "pleasingly plump"; whether a man is called "generous" or "spendthrift," "thrifty" or "stingy," "conservative" or "a mossback reactionary," "liberal" or "radical"; whether he is said to have "the courage of his convictions" or to be "as stubborn as a mule." A college student appreciates being told he has the power of concentration but resents being called a "dig" or "grind." No doubt the central character in the Bible's best known parable was often flattered, so long as his money lasted, by the ancient equivalent of "He's a jolly good fellow" before he was immortalized as the Prodigal Son.

To most doctors, doubtless the first and most important meaning of the word "research" is work done in a great laboratory with thousands of dollars' worth of apparatus. The second idea suggested is a large hospital, with hundreds of patients separated into two great groups labeled "test" and "control." Perhaps a third conception is some such project as was recently completed by the United States Public Health Service, aided by one of the alphabetical arrangements of the federal government, in which a survey of nearly 800,000 families in the nation was made in order to find out what any intelligent high school student could have predicted—that there was more sickness in the families on relief and with annual incomes of less than \$1,000 than in the upper income group. Apparently the conclusion was reached—which the same high school student would know is erroneous—that the only remedy needed is to have as many doctors' visits made to the low income group as to these in the higher brackets. While this conclusion is extremely flattering to our profession, none know better than we how sadly this

low-income group needs sufficient food and warm clothing and adequate houses and fuel even more than it needs doctors' visits.

The average family doctor is likely to be so overawed by the majesty of the word "research" that he refuses to entertain for a moment the thought that he himself is capable of doing it while engaged in active practice. In truth, however, he is in a better position to do clinical research because he is in practice. Instead of working with rats, rabbits and guinea pigs, he has at hand the finest material in the world to use for study—the human beings who come to him for treatment. One can carry on one bit of investigation after another, or work on a number of problems together, and do better work for having a stimulating new interest added to the daily routine of practice. An utterly false conception of research is that it makes a man cold, heartless and indifferent to human suffering.

Before we tamely submit to the tyranny of the fearsome word "research," let us see just what it does mean. According to the Standard Dictionary, Webster concurring, it means "diligent protracted investigation, especially for the purpose of adding to human knowledge; studious inquiry." "Clinical," of course, is derived from the Greek word "klinikos," meaning "of a bed," with a second less aristocratic choice of ancestry in the Low Latin "clinicus," meaning "bedridden person." Our title, then, means "a studious inquiry of bedridden (or sick) people." Certainly every general practitioner worth his salt does just that every day of the week, including Sunday. It is the first part of the definition that may be forbidding at first glance; but closer inspection should make us feel more kindly toward it. Surely every doctor with a puzzling professional problem in the form of a serious, long drawn out illness will make "diligent protracted investigation" into the cause and (if possible) cure of his patient. When he has found the answer, if his experience will help other doctors solve similar problems, of course he will want to share his knowledge with his colleagues by telling them about it, thereby "adding to human knowledge" and engaging in "research" unawares. If, instead of a single patient studied intensively, a series of similar cases offers an opportunity to compare different methods of treatment or to evaluate a new remedy, a statistical study forms the basis for research of a different sort, but also valuable. Then, if the doctor extends his audience from a few friends to the county, district or state society or a medical journal—or both—he is indeed "adding to human knowledge." Any one who has ever done any bit of investigation knows that he himself profits more than anybody else. It is almost, if not quite, an invariable rule that he who tries to teach others will learn far more than he will teach.

THE ABILITY OF FINDING VALUABLE
THINGS UNEXPECTEDLY

I wish that every doctor in North Carolina could have heard Dr. Milton J. Rosenau's address to the State Public Health Association last year on "Serendipity." Let me hasten to explain that Serendip was the name that Marco Polo gave Ceylon and that Dr. Rosenau got his title from a fairy story of three princes of Serendip who "went about the world seeking adventures and making discoveries, by accident and sagacity, of things they were not in search of."

The doctor who carries into the practice of medicine something of serendipity will be repaid many times over; but he should also remember and absorb the famous saying of Pasteur "Chance favors the prepared mind" and have his mental antennae tuned to catch any important message that may come his way. It was the prepared mind and the spirit of serendipity that enabled Ambroise Paré to forsake the brutal method of dressing gunshot wounds with boiling oil; that made William Withering learn from an old woman the value of digitalis; that impelled John Hunter to do his pioneer work in surgical pathology and to elevate surgery from a trade to a profession; that gave to us through Jenner vaccination against smallpox; that caused William Beaumont to turn a French-Canadian's gunshot wound into an opportunity to study the physiology of gastric digestion; that led Crawford W. Long to use ether for anesthesia; that made Oliver W. Holmes and Semmelweis grasp the true explanation for childbed fever; that inspired Pasteur in his many brilliant discoveries; that gave Koch his triumphant discovery of the tubercle bacillus; that opened Roentgen's eyes to the wonderful possibilities in a Crookes tube. Coming to more modern times, the prepared mind of George Minot found a cure for pernicious anemia; Banting's isolated insulin; von Jauregg's recognized the value of malarial paroxysms in dementia paralytica; our own William MacNider's has made him an international authority on the kidney; our own David Smith's has taught us to treat pellagra and staphylococcic septicemia.

The family doctor in the small town or rural district has at least one distinct advantage over the hospital worker: his practice is a much more stable one, and it is easier to follow up his cases and so evaluate the results of treatment. His patients are also apt to be more intelligent and so more cooperative than are those who come to the wards and dispensaries of a great hospital. Those who have heard Dr. Walter C. Alvarez talk must have been impressed by the emphasis he places on the use of one's five natural senses, plus the priceless ingredient of common sense. Moreover, while the country doctor may not have the elaborate facilities of a great laboratory, he should have a few test tubes, a Bunsen burner or alcohol lamp, a microscope, a blood counting apparatus, glass slides, a few stains and the chemical reagents required to make the simple tests often needed to confirm a clinical diagnosis. Wassermann tubes are to be had for the asking, and the state laboratory sends reports promptly not only on Wassermann tests but also on typhoid, undulant fever and other serologic examinations.

With such aids to an adequately taken history and a complete physical examination, the family doctor should be able to diagnose and treat most of his patients himself and to know when the help of a surgeon or specialist is needed. Then if he will train himself from the beginning to keep records of his patients, he will be

laying the foundation for one piece of research after another. The habit of keeping in mind for study some problem, or even several problems, adds immeasurably to the zest of practice. It gives the spice of adventure to what may otherwise become deadening routine. Furthermore, the answer to a hard professional riddle may be found because one has the riddle in mind. Only too many of us are like the Negro who, when something was explained in terms he could understand exclaimed "Why, I never thought to think about that." Recently a brilliant research worker in physics said that when any important discovery in physics is announced it is at once tried out in his laboratory. Almost invariably he finds it easily duplicated with his apparatus. All that was necessary was the thought to think about it. The same thing could be said of many, if not most, great medical discoveries.

ESSENTIALS FOR CLINICAL RESEARCH

Oliver Wendell Holmes said that in Paris he learned three things from the great Louis: "Not to take authority when I can have facts, not to guess when I can know, and not to think a man must take physic because he is sick." These three principles are to be commended to every doctor as essential for true clinical research. Certainly no one should be satisfied to guess at the answer to any problem when it is possible to know, even though the solution requires some effort. And no matter how much any man may tower above his colleagues, his mere prestige does not make him infallible. The tremendous weight of Galen's authority kept the medical profession in the Dark Ages for more than a thousand years. But for the great force of Dupuytren's name—coupled, it must be confessed, with his brutality—appendicitis might have been recognized as a clinical entity when Melier first described it in 1827, nearly sixty years before Reginald Fitz's classic description of it was published. Fortunately the great Pasteur, in spite of his gentle nature, had enough native resolution under the surface successfully to oppose the die-hard authorities of his day and so to deserve the honor of fathering modern medicine.

Now, happily, while any new work is subject to keenly critical evaluation, we do not see the savage assaults on all new ideas or the jealous distrust of the younger members of the profession that prevailed in the days of Dupuytren and Pasteur. It is fortunate that new methods of diagnosis and treatment do have to run the gantlet of critical study; for thereby is the public protected from excessive enthusiasm, which Da Costa once said is "as dangerous as prejudice." It is true, however, that never in the world's history has the medical profession been so quick to assimilate and utilize new knowledge. In an incredibly short time, sulfanilamide has made a large place for itself. Just as soon as insulin could be standardized and placed on the market, it was being used all over the world. The value of liver in the treatment of pernicious anemia was speedily reflected in the soaring price of that hitherto humble article of diet. The serum treatment of pneumonia is being widely used and there is great interest in the exciting possibility that the x-rays may prove just as effective and far less taxing to the patient, physically as well as financially.

THE SHARING OF DISCOVERIES

One of the glories of the medical profession is that its members have no trade secrets. When any doctor, no matter whether a professor in a great medical school

or a general practitioner in an obscure rural section, makes a discovery that may benefit humanity, it is his duty to acquaint other doctors with it. With the multitude of medical journals now published, there is no valid excuse for any man to withhold any information he may have in return for what he learns from others. The two chief deterrents are false modesty and laziness.

Those who have read Marion Sims's fascinating story of his own life will recall his experience with his first published case report. He had operated for a double harelip and obtained such a remarkable result that a dental friend begged him to write a description for the *Journal of Dental Surgery*. When Sims objected that he had never written anything in his life, the dentist gave him the excellent advice "Write it as you would talk it, or as you have told it to me." When the journal with his article came, it was hidden behind some large books in his office. To his great dismay, some months later Dr. Ames, the leading practitioner of Montgomery and the most prolific writer, while on a social visit walked over to the bookcase, took down the volume that hid the dental journal, pulled it from its hiding place and began turning its leaves. Now let Dr. Sims¹ tell the story:

"I said to myself, 'My God! if he goes on in this way, he will come to the article on the "Lowndes County Girl's Harelip," and he will give me fits.' I was trembling like a leaf, as I stood there like a school boy. Still he stood there, turning over leaf after leaf, and when he got to where the case was described, he did not look up at all, or say a word, but stood there, reading it down on the first page, then on the other page, deliberately reading it through. It just occupied two pages. My heart was in my throat. As he finished the article he stood perfectly still, and I also stood perfectly still, trembling. As he turned around I thought, 'I shall get it now.'

"In a moment he said, 'What would I give if I had the faculty of expressing myself in writing like that?'"

No doubt Dr. Sims was quite sincere in his description of the agony of embarrassment he suffered; yet he was well repaid by the commendation of his colleague. A far higher reward, however, was the feeling that he had added to human knowledge.

In contrast, let me tell a story of how a country doctor narrowly missed fame and—far more important—an opportunity to save thousands of children's lives. Last summer a loquacious old lady, well past three score and ten, told me that her old family physician, a Dr. Anderson, who died some years ago in Iredell County, lost his first baby of cholera infantum. When his next child reached the second summer, it acquired the same ailment, was desperately ill for a few days, then began improving. One day he came on the baby's old colored nurse feeding it scraped apple. He began to berate her soundly, asking why she wanted to kill this baby after he had already lost his firstborn. "Well, doctor," she replied, when he paused for breath, "your baby is getting better, isn't it?" When he admitted that it was, she continued, "That's because I've been feeding it scraped apple. If you want it to get well, please let me keep on." Grudgingly he had to admit the force of her argument and agreed for her to go on with the treatment. Within a few days the baby was well, and so long as he lived

thereafter the good doctor used scraped apple regularly and successfully in diarrhea and dysentery. This was forty years before Birnberg published his first report in America of this now famous therapy. It is highly probable that Dr. Anderson's sense of modesty kept him from asking for a place on his medical society program or writing a report for a medical journal, in order to acquaint the world with his life-saving discovery; yet it was his duty to do so. He failed to obey the Scriptural command "Let your light so shine before men, that they may see your good works."

Laziness, I fear, is responsible for more sins of omission in recording our observations than is modesty; and by a process of rationalization it is easy to deceive oneself into thinking one is too modest to write when one is really too lazy. Every one who does any writing, even on a small scale, knows it is hard work; yet its difficulty is often exaggerated. The story is told of a cub reporter who had uncovered his first big story but was afraid he could not do justice to its news value. As he sat before his typewriter mopping his brow, a veteran noted his plight, walked over and, patting him on the shoulder, said "All you have to do, son, is to put down one little word after another." With a story to tell, any man with enough knowledge of the English language to get a medical diploma should be able to write it. The veteran reporter's wisdom was shown when he used the adjective "little" before "word." Oliver Wendell Holmes has aptly said "Never use a long word where a short one will serve the purpose. I know there are professors in this country who always 'ligate' arteries. Other surgeons only tie them, and it stops the bleeding just as well."

Soon after the "Life and Letters of Walter H. Page" was published, a friend gave me a copy at Christmas. While reading it, my 6 year old daughter came up behind me. She had been in the first grade four months and was anxious to use her new knowledge. "Daddy," she said, "let me see what I can read." For curiosity, I made a rough estimate of what she could understand and was surprised to find that she recognized about 70 per cent of the words used in one of Page's letters. I am not telling this story to show that I am the father of a child prodigy—God forbid!—but as proof that one of the world's greatest scholars ordinarily used words so simple that a first grade pupil could understand most of them. It helps us to clarify our own thoughts if we clothe them in the simplest language possible, and certainly it will help our readers to grasp them.

THE NEED OF RESEARCH

It is fortunate for many generations of his students as well as for his patients that the master clinician and teacher David Riesman² outgrew a youthful notion thus charmingly described by him: "A good many years ago a friend and I were . . . discussing the physical diagnosis of the heart. In our youthful ignorance we agreed . . . that it was a closed chapter, that all was known that ever could be known, and we had best devote our untapped energies in physical diagnosis to some other branch of medicine if we wanted to make discoveries. Little did we think that in a small provincial town in England a man at that very moment was blazing a new path in cardiac diagnosis, and that his work was to revolutionize a subject we

believed to be perfect and unchangeable." In 1829 Andral wrote² "Since the publication of the immortal researches of Corvisart, and of numerous other works subsequent to his, which have still further enlarged the dominion of science, the history of diseases of the heart and its membranes is to be regarded as almost complete."

To any one who may feel that there is no further need for research, it is only necessary to suggest a few unsolved problems waiting for some Jenner, Pasteur, Banting or Minot: arthritis, asthma, hay fever, urticaria, migraine, epilepsy, peptic ulcer, spastic colitis, the common cold, sinusitis, granulopenia, essential hypertension, coronary heart disease, nephritis, ureteral stricture, encephalitis, much mental disease—and only too many others.

Doubtless the answer to many of our problems is as simple as was the liver treatment of pernicious anemia or the malarial treatment of dementia paralytica; yet it may be years before many of them will be solved. Others will require long, patient and persistent effort, in which some bit of keen observation by one of us may be as essential as the keystone to an arch. While occasionally an important discovery may be made by a brilliant flash of inspiration, far more are made by patient repetition of trial and error. Even the best will have more errors than successes; but the errors are soon forgotten while the successes are remembered. "We learn wisdom from failure much more than from success. We often discover what *will* do, by finding out what will not do; and probably he who never made a mistake never made a discovery" (Samuel Smiles).

The classic modern example of clinical research by a general practitioner is, of course, the research of Sir James Mackenzie. Soon after entering practice in the little Scotch village of Burnley he lost a young woman in childbirth from sudden heart failure. This harrowing experience made him resolve to learn all he could about heart disease, so that, if possible, he could avoid another such tragedy in the future. Finding little help in the literature available he began studying his patients themselves. For a score of years he kept accurate histories of all with cardiac irregularities. In order to record graphically the various types of pulse beats, he devised a crude but effective instrument for making pulse tracings on strips of smoked paper fastened to a revolving drum—a modification of the old Dudgeon sphygmograph, which he called the ink polygraph. At the end of twenty years he could say with authority which types of irregularity were dangerous and which were not. Then he began to publish the results of his study. First came a modest little volume called "The Study of the Pulse." Later he moved to London and published his monumental work, "Diseases of the Heart." He was literally forced into becoming a heart specialist and before his death was generally recognized as the one who had added more to our knowledge of the heart than any man since Harvey discovered the circulation.

Mackenzie had the great advantage, which he often emphasized, that he could follow his cases for periods of time impossible to those depending for clinical material on the floating population of a hospital or on the more unstable clientele of a city practitioner. He also often stressed the point that one could far more intelligently study one particular organ if one was familiar with the functions of the whole body.

Sir James used the same methods as did Hippocrates, who four centuries before Christ placed medicine on the highest plane it was to occupy until modern times. Instead of wasting his energy in useless speculation, Hippocrates studied every patient, recorded his observations, and compared results. It is an intriguing, though futile, speculation as to how many lives might have been saved had the medical profession followed his sane leadership instead of accepting as inspired the dogmatic statements of Galen. The really modern scientific method of observation taught and practiced by Hippocrates was forgotten in the blind worship of Galen's authority, and millions of lives were sacrificed on this altar.

One of the finest examples of surgical research by a general practitioner was that of J. Marion Sims. His prepared mind made one brilliant discovery after another; but his greatest "diligent protracted investigation for the purpose of adding to human knowledge" was learning to cure vesicovaginal fistula. While busy with a large general practice, he used all his spare time for four years in repeated operations on a few Negro slaves whom he kept at his own expense. One method after another failed. When his colleagues grew tired of assisting him, he trained the patients themselves to help. At length his family and friends begged him to give up a senseless undertaking before it ruined his practice and wasted all his financial resources. He persisted, however, and at long last the thirtieth operation on the Negro Anarcha was successful. In rapid succession others were cured of this distressing malady, and the foundation for the worldwide fame of Sims was laid. Years later he traveled abroad in a veritable triumphal march, operating in some of the most famous hospitals and on some of the most famous patients in Europe. He and other apparently tireless workers verify Matthew Arnold's definition of genius as "mainly an affair of energy" and the observation of Sir Joshua Reynolds that "If you have genius, industry will improve it; if you have none, industry will supply its place."

The temptation is to multiply examples, but time marches on and these are enough. I should like to tell of the numbers of papers read at various district meetings during the past year that showed the spirit of research. Some of the best came from small towns and rural communities. Rather than run the risk of discrimination, I shall not mention any by name. The past year has been one of the most profitable of my life, in that my travels over the state have afforded a continuous postgraduate course. Judging by the uniformly high order of the papers read in every district, the intelligence of the discussions, the eagerness of those attending the postgraduate courses and the spirit of research shown by so many of our men, the health of the people of North Carolina is in good hands.

A Sick Pocketbook.—In other words, a sick pocketbook is more responsible for ill health than are certain supposed deficiencies in our system of providing medical care. These deficiencies can be corrected without disturbing the patient-physician relationship and without the injection of politically controlled third parties. In Pennsylvania, seventeen counties have had systems in operation which have proved to be efficient and economical. It is not necessary to build up elaborate departments to dispense medical services.—Borzell, Francis F.: *The Medical Profession and the Social Worker, Pennsylvania M. J.* 41:683 (May) 1938.

SITES OF METASTASES FROM CARCINOMA OF THE ANUS, RECTUM AND SIGMOID COLON

HARRY E. BACON, M.D.
ANDPHILIP D. GILBERT, M.D.
PHILADELPHIA

Except for a few individual reports, comparatively little has been written on the occurrence of metastases from malignant growths in the lower portion of the large bowel. For this reason, in order to discuss this subject on a factual basis, we have reviewed the records from the radiologic department of the Philadelphia General Hospital for the ten year period ending with 1936.

In 318, or 77.7 per cent, of a series of 409 cases of malignant process of the large bowel in which there was metastasis to one or more organs, as evidenced by biopsy, celiotomy, roentgenograms or necropsy, the primary site was in the anus, rectum or sigmoid colon. This confirms the observations of Larson and Nordland,¹ Heyd² and Rankin³ that metastasis is encountered more frequently with malignant growths in these parts than with such growths in the upper portion of the large bowel. In our series the primary growth was located in the rectum in 239 cases, in the sigmoid in seventy-five and in the anus in four.

Much discussion has taken place concerning the relationship between the clinical type, the size of the growth and lymphatic metastasis.

Omitting the histologic types of tumors, one may say that, just as a papilliferous growth is less liable to become malignant than one that is sessile, so metastasis is encountered less frequently when a malignant growth protrudes into the lumen (papilliferous carcinoma) than when it invades the wall. This has been observed by Craig and MacCarty,⁴ Dukes,⁵ McVay⁶ and Hayes.⁷ In 267, or 80.8 per cent, of our series of 318 cases, the growth was described as sessile.

McVay⁶ has shown that the size of the tumor cannot be relied on as an accurate index to the probable lymphatic involvement. Dukes expressed the opinion that there is no relationship between the surface area of the growth and the depth of penetration, because a large proliferating cancer may almost entirely occlude the lumen of the rectum yet be confined to the mucosa and submucosa, whereas a relatively small ulcerating lesion may have spread to invade the extrarectal tissue. In the series cited no attempt was made to measure the growth in the transverse or the longitudinal diameter, but it was observed that in all 267 cases at least three quarters of the circumference was involved.

This brings up several points for discussion. For instance, it has been observed that the spread of cancer of the rectum by continuity of tissue is a slow process.

Handley⁸ many years ago cited a case of rectal carcinoma in which, by staining of an entire section of bowel with mucicarmine, continuous spread was demonstrated in the submucosa beyond the gross limits of the tumor. He concluded that metastasis by this means occurs early and is frequent. Others, notably Cheatle,⁹ Cole¹⁰ and Monsarrat,¹¹ were unable to confirm these observations and concluded that this was a rare case. Leitch¹² went so far as to repeat the experiment, using mucicarmine in a considerable number of cancerous rectums, but failed to find stained cells in the submucosa except for those which he believed were the ganglionic cells of Auerbach's plexus. At any rate, spread by continuity of tissue is undoubtedly a slow process.

Lymphatic metastasis is more rapid; according to Miles¹³ it occurs by means of the intramural lymphatic system and, after invading the external network, gives rise to extramural metastases long before the muscular coat has been penetrated by direct extension. Lockhart-Mummery,¹⁴ on the other hand, expressed the opinion that invasion of the lymphatics occurs only after penetration of the muscular coat. Dukes⁵ and Gordon-Watson¹⁵ concurred in the belief that such invasion is not found until the cancer has spread by direct continuity through the rectal wall into the extrarectal lymphatics. Examination of serial sections of the involved rectal wall and contiguous and extrarectal tissues was not possible in this series of cases.

No attempt was made to determine the duration of the growth by computing the period between the date on which the lesion was first recognized and the time at which metastasis became apparent. We did employ a less accurate method, that of adding six months to the period between the onset of symptoms and the time at which both local and remote metastases were noted. As previously reported,¹⁶ the average period from the onset of symptoms to recognition of the cancer in 1,031 of a possible 1,995 cases was nine months and three weeks. In this series of 318 cases, the average period between the onset of symptoms and the observation of extension or regional metastasis was eleven months and two weeks, whereas the average period between the onset of symptoms and observation of distant metastases (lungs, pancreas, vertebrae, spleen, renal capsule and heart) was nineteen months. If six months is added to each figure, the growths showing regional metastases had existed for seventeen months and two weeks, while those showing distant metastases had existed for twenty-five months. This closely parallels the estimated period of duration as expressed by Miles,¹⁷ in that growths involving three quarters of the circumference of the intestine had existed eighteen months or longer, for it will be recalled that they had done so in 267 cases of our series.

The distribution as to age, sex and race is shown in table 1, and the sites of metastasis and local extension (in order of their frequency) are listed in table 2. Other sites of metastatic involvement not found in this series have been reported; they include the umbilicus,¹⁸ ureter,¹⁹ eye,²⁰ humerus,²¹ clavicle,²² sternum,²³ radius,²³ ulna²³ and supraclavicular nodes.²⁴

TABLE 1.—Distribution as to Age, Sex and Race

Age	Number	Sex	Number	Race	Number
10-20.....	1	Males.....	202	White.....	309
21-30.....	13	Females.....	116	Negro.....	8
31-40.....	36			Chinese.....	1
41-50.....	35				
51-60.....	85				
61-70.....	92				
71-80.....	52				
81-90.....	4				

A few decades ago Mayo²⁵ and McArthur²⁶ observed that the liver is usually the first remote organ affected. Pruitt²⁷ has estimated the frequency of hepatic metastasis to be 40 per cent, and while our percentage is similar to this it must be remembered that this report is based only on cases in which there was metastasis. So far as metastasis to lymph nodes is concerned, the large series of 1,112 cases reported by Buday²⁸ and Reichelmann²⁹ is worthy of mention. As cited by Pennington,³⁰ these two authors found involvement of the regional lymph nodes in 336 cases, or 30 per cent, and of the distant nodes in sixty cases, or 5.3 per cent.

Bargen and Larson³⁰ in a series of 260 cases noted the following involvement (verified by microscopic examination in 113, or 43.4 per cent): perirectal, seventy-one cases; mesenteric, fifteen; inguinal, fourteen; iliac, five; aortic, five; axillary, two, and omental, one.

Compared with these figures, the percentage of regional glandular involvement in our series is low (31.1). It should be remembered, however, that all the regional nodes were not removed or examined in each individual case. Quite recently, Brown and Warren³¹ found that in twenty-four, or 34 per cent, of seventy cases in which there was visceral metastasis, the lymph nodes failed to show involvement.

Aufses²¹ confirmed von Recklinghausen's³² order of metastasis to bone from carcinoma of the rectum as follows: vertebra, femur, ribs, skull, sternum, humerus, pelvis, sacrum, radius, scapula and ulna. In our series of cases, however, the order of frequency was sacrum, coccyx, pelvis, lumbar vertebra, dorsal vertebra, femur, ribs, skull, cervical vertebra and shoulder girdle.

Rankin³³ and Broders³⁴ observed a parallelism in the ratio of glandular involvement and the grade of malignancy and also that the absence of metastasis increases in inverse ratio to the grade of the malignancy.

The grade of the tumor and its relationship to metastasis in 260 cases of rectal carcinoma as cited by Broders³⁵ are as follows: eighty-two cases (14.65 per cent) of grade 1 cancer, with metastasis in 26.82 per cent; 290 cases (51.78 per cent) of grade 2 cancer, with metastasis in 44.13 per cent; 137 cases (24.6 per cent) of grade 3 cancer, with metastasis in 56.2 per cent, and fifty-one cases (9.1 per cent) of grade 4 cancer, with metastasis in 64.7 per cent.

These figures are consistent with those of Karsner and Clark,³⁶ except for grade 1: two cases of grade 1 cancer, with metastasis in 100 per cent; twelve cases of grade 2 cancer, with metastasis in 75 per cent; seventeen cases of grade 3 cancer, with metastasis in 76 per cent, and seven cases of grade 4 cancer, with metastasis in 100 per cent.

On the other hand, in our series of 318 cases, in all of which there was metastasis, the grade of tumor according to Broder's classification was noted as follows: twenty-one cases, or 6.6 per cent, grade 1 cancer; 165 cases, or 51.9 per cent, grade 2; 117 cases, or 36.8 per cent, grade 3, and nine cases, or 2.8 per cent, grade 4. In six, or 1.9 per cent, the grade was not stated.

It is apparent that there is a vast difference in the series, which in itself deserves some explanation. It

must be remembered that, first, several pathologists have reported on the gradings and, secondly, only a few specimens were examined serially. The second factor is important because we know that the arrangement and the differentiation of the malignant cells of rectal carcinomas are not uniform throughout the growth. It may also be mentioned, as in the cases cited by Dukes,³ that fragments removed for diagnosis differed in grade from the specimens excised at operation. Dukes noted also considerable discrepancy between the grade according to cell differentiation and the extent of spread. In discussing malignancy of the breast, Pfahler quoted Dawson and Tod³⁷ as follows: "These microscopic

grades of malignancy can only be determined after complete operation and study of the entire breast. While there is a general microscopic appearance in these tumors which permits classification . . . some characteristics of all these grades are apt to be found in some part of each tumor." Reimann³⁸ remarked: "The various grades of malignancy can be found in at least half the tumors encountered in a series such as we have at our hospital and probably 75 per cent if sufficient number of sections are taken from different areas." MacCarty³⁹ stated that different portions and even different areas in the same microscopic field show a different grade; the grades of the primary and of the secondary tumor vary; recurrent tumors are often different in grade from the primary tumor, and different grades have different criteria.

In comparing the grade of cancers in the upper and in the lower portion of the large bowel, Karsner and Clark³⁶ noted a much higher incidence of grades 3 and 4 in the former location. In our series there were 409 cases of malignant growth in the large bowel with metastasis; in 318 the process was in the anus, rectum or sigmoid colon and in eighty-one in the upper portion of the large bowel. In fifty-two of these eighty-one cases the grade of cancer according to Broders' classification was reported; in twenty-eight, or 53.8 per cent, the cancer was of grade 2; in sixteen, or 30 per cent, it was of grade 3, and in eight, or 15.4 per cent, it was of grade 4.

SUMMARY

In 318, or 77.7 per cent, of a series of 409 cases of malignant growth in the large bowel, in all of which there was metastasis, the primary site was in the rectum, sigmoid colon or anus.

In 267, or 80.8 per cent, the tumor was described as sessile. In the 267 cases, regardless of the type of tumor, approximately three quarters of the circumference of the bowel wall was involved.

In 318 cases the average period between the onset of symptoms and the observance of regional metastasis was seventeen months and two weeks, whereas the average period between the onset of symptoms and the observance of distant metastasis (e. g., to the liver or lung) was twenty-five months.

The greatest number of cases of primary cancer of the large bowel occurred during the fifth, sixth and seventh decades, men being more frequently affected than women.

Visceral metastasis was most prevalent in the liver, ranking first, with 40 per cent; metastasis to regional lymph nodes came next, with 31.1 per cent; with bony metastasis, the order of frequency was sacrum, coccyx, pelvis, lumbar vertebrae and so forth.

According to Broders' classification, in the greatest number of cases in our series, in all of which there was metastasis, the cancer was of grade 2 (51.9 per cent). In 36.8 per cent it was of grade 3.

CONCLUSIONS

Metastasis is more frequently encountered with a malignant growth in the lower portion of the large bowel than with such a growth in the upper portion.

Sessile growths are more prone to metastasize than papilliferous growths.

There is a period of approximately eight months between the first recognition of the tumor and the observance of regional and distant metastasis.

We were unable to support the contention that the percentage of metastases always is greater for the higher grades of malignancy.

Our studies show a predominance of grade 2 tumors.

THROMBOCYTOPEN

A SUBSTANCE IN THE EXTRACT FROM THE SPLEEN
OF PATIENTS WITH IDIOPATHIC THROMBO-
CYTOPENIC PURPURA THAT REDUCES
THE NUMBER OF BLOOD
PLATELETS

CHARLES E. TROLAND, M.D.

AND

FERDINAND C. LEE, M.D.

BALTIMORE

The purpose of this article is to describe more fully an extract obtained from the spleen of patients suffering from idiopathic thrombocytopenic purpura which reduces the number of platelets in the circulating blood. A brief preliminary report has already been published.¹ All the material was obtained through the cooperation of Dr. Dean Lewis, who felt that it might be possible to make extracts of such a nature that the clinical picture of the disease could be reproduced experimentally.

MATERIAL AND METHOD

Chronologically, the first successful extract was made from the spleen of a patient, the essential points in whose case are as follows:

CASE 1.—M. O., a white woman, aged 22, was admitted to the Johns Hopkins Hospital on Jan. 25, 1937, because of rectal bleeding. The family history revealed no excessive bleeding or blood dyscrasia. She was first admitted to the hospital in 1933, at which time an appendectomy was performed. The operation and convalescence did not indicate a hemorrhagic tendency. The early history did not suggest any tendency to excessive bleeding. The menstrual history was normal, with each period lasting for three to four days and only moderate flow. In August 1936, during the fourth month of her first pregnancy, the patient noted spontaneous bleeding from the gums in small amounts. In November some small purpuric areas were noted on the abdomen, but they disappeared in two days. These purpuric spots continued to appear at weekly intervals throughout the remainder of the pregnancy. Blood studies showed normal cell counts. On December 18 a blood smear showed the number of platelets to be greatly reduced. A rectal examination in the Obstetrical Dispensary on Jan. 25, 1937, caused excessive bleeding, and the patient was admitted to the hospital. Two hundred cc. of blood and 0.6 cc. of snake venom were given on the day of admission and again on the following day. On January 27 she was delivered of a normal child, with hemorrhage estimated to be only 150 cc. Blood studies on the day of delivery showed platelets 78,000 and red cells 4,000,000 per cubic millimeter, hemoglobin content 12 Gm., bleeding time eight minutes and reaction to the tourniquet test positive. Some vaginal bleeding began on February 1 and continued for a month, during which time purpuric spots again appeared on the abdomen. On March 1 large clots of blood were passed, and this form of hemorrhage continued until April 8. From March 12 to March 19, three blood trans-

fusions were given, as well as four injections of snake venom in doses varying from 0.6 to 1 cc. Bleeding did not stop. The platelet count remained around 36,000, and the hemoglobin content dropped from 12 to 5.8 Gm. On April 8 splenectomy was performed by Dr. Paul A. Kunkel. Vaginal bleeding ceased, and blood studies on April 20 showed the platelet count to be 280,000, bleeding time one and one-half minutes, red cells 4,170,000, clotting time nine minutes and clot retraction time one hour. The patient was discharged on April 22. Blood studies on May 12 showed the platelet count to be 112,000, bleeding time four minutes, clotting time seven minutes, clot retraction time forty-five minutes and hemoglobin content

Chart 1.—The fall and subsequent rise to normal of the number of platelets in the circulating blood of a rabbit after the intravenous injection of 20 cc. of splenic extracts obtained from three patients with idiopathic thrombocytopenic purpura.

13 Gm. She was readmitted on May 25, complaining of pain in the right upper quadrant, which was diagnosed as due to acute cholecystitis. She was discharged on May 27. Since the splenectomy there has been no evidence of excessive bleeding.

The spleen weighed 120 Gm. and was smooth, soft and glistening. Microscopic examination revealed conspicuous malpighian bodies but only occasional germinal centers. The sinuses were partly filled with blood. There were no abnormal cells in the pulp, and there was little evidence of blood destruction.

The spleen was cut up and placed in five volumes of acetone. Dr. Arthur Grollman suggested that reagent acetone be used and not the commercial variety. The specimen was shaken occasionally from the time of removal on April 8 until June 4, when the acetone, which by that time was a light orange, was filtered off. Commercial acetone was put back on the ground-up spleen, primarily to preserve it but also with the idea of seeing whether this type of acetone could be used for extraction.

The filtered acetone from the first extraction was distilled off, leaving a brownish sediment on the walls and bottom of the balloon flask. One hundred cc. of distilled water was poured into the flask and shaken vigorously in order to take up as much as possible of the brown residue. The cloudy brown fluid was filtered through filter paper, and the small amount of fatty dark brown material remained on the paper. The filtrate was cloudy and orange-brown. It was put on the ice at once and never showed a precipitate.

Before any tests were made of the first extract, and therefore without its being known whether the acetone extract was of any value, the spleen from the second patient with thrombocytopenic purpura was received. The essential features of this patient's history are as follows:

CASE 2.—F. D., a white girl, aged 14 years, was first seen in the Harriet Lane Home of the Johns Hopkins Hospital in 1923, when 3 months of age. The family history revealed no

excessive bleeding or blood dyscrasia. A hard purple swelling had appeared on the right side of the face at the age of 6 weeks and had gradually grown to include the right ear and the right side of the neck. She was referred to the Howard A. Kelly Hospital, where radium treatments were given for one and a half years. The purple area disappeared completely. During the next seven years she had the usual childhood diseases, measles, pertussis and chickenpox. In 1930 a tonsillectomy and an adenoidectomy were performed without excessive bleeding. The menses first appeared in February 1936, with profuse bleeding, and coincidentally with their appearance the purple mass on the face and neck reappeared. Radium treatments were again resorted to, and the mass promptly disappeared. On October 19, five days before the onset of menstruation, the purple swelling reappeared, but it disappeared when menstruation began. This same phenomenon recurred in three week cycles, and during the period of greatest swelling there was some respiratory embarrassment, which became pronounced on December 30, and she was admitted to the hospital.

Examination showed the right side of the face and neck to be greatly swollen, and there were extensive hemorrhages into both eyelids and from the buccal mucous membranes. Difficulty in breathing was moderately severe but not enough to justify tracheotomy. Blood studies showed the platelet count to be 198,000 per cubic millimeter, the reaction to the tourniquet test positive, red cells 4,360,000 and hemoglobin content 13.8 Gm. Diagnoses of hemangiosarcoma of the face and thrombocytopenic purpura were made. The patient's condition gradually improved, and she was discharged on Feb. 12, 1937. She was readmitted on February 22, because of respiratory difficulties caused by the swelling of the right side of the face and neck. Blood studies showed the platelet count to be 128,000, but extravasation of blood around the venous puncture needle prevented further studies. She was discharged on March 7 but was again readmitted on March 19. Seven days after discharge she had received a blow on her ankle; a marked extravasation of blood promptly appeared. Her gums bled spontaneously. Blood studies on March 19 showed platelets 21,000 and red cells 4,680,000 per cubic millimeter, bleeding time thirty minutes, clotting time five minutes, clot retraction time twenty-four hours and reaction to the tourniquet test positive. Her condition improved and she was discharged on May 6.

On June 11 the patient was readmitted, with identical complaints. Splenectomy was performed by Dr. Barnes Woodhall on June 28. A small accessory spleen was found and removed.

Chart 2.—The hourly change in the number of platelets in the circulating blood of a rabbit after the intravenous injection of 3 cc. of a splenic extract obtained from a patient with idiopathic thrombocytopenic purpura.

transfusions. On September 3 the swelling of the neck became pronounced and breathing difficult. On the following day there were epistaxis and progressive respiratory embarrassment. The patient died on September 4 after tracheotomy.

The spleen weighed 131 Gm. and was smooth and glistening. It was moderately tense on section. Microscopic examination showed marked fibrosis and a scarcity of cells in the pulp. Malpighian bodies were conspicuous, but only rarely were germinal centers seen. Numerous vessels showed hyaline changes, and there was a suggestion of the sickle cell trait. The accessory spleen showed marked hyaline changes in the vessels.

On the day of splenectomy, June 28, 1937, the spleen was ground up in a food chopper and, again empirically, placed in reagent acetone, as was the first spleen.

At this time no tests with the extract from the first spleen had been carried out, but extensive control platelet counts had been made in order to insure uniformity and reliability of the technic. The direct method of counting platelets was utilized throughout, the fluid of Rees and Ecker being used and the indirect blood smear method being employed for frequent checks on the direct counts.

Chart 3.—The effect on the number of platelets in the circulating blood of a rabbit of repeated intravenous injections of a splenic extract obtained from a patient with idiopathic thrombocytopenic purpura.

On July 16 the first injections of the acetone extract from the spleen of patient 1 were made. A stock rabbit was used as the test animal, primarily because of simplicity and convenience. In all cases a new rabbit was used for each injection. After the normal control platelet count was made, 5 cc. of the first extract, known as S-1, was injected into the marginal vein of the ear of this rabbit, which weighed 2 Kg. When no untoward reaction occurred in five minutes, 15 cc. more of the same extract was injected into the same vein. The platelets steadily fell from their preinjection level of 620,000 per cubic millimeter to 58,000 in eight hours (chart 1). At this low level of platelets it was noted that bleeding was difficult to check when the ear was stuck. No purpuric spots, however, were noted at any time. The platelet count twenty-four hours after injection was 58,000 per cubic millimeter, but it rapidly rose in six hours to 610,000.

On July 27 an injection of 14 cc. of the same extract, S-1, was made into the marginal vein of the ear of a second rabbit, which weighed 2.2 Kg. The platelet count fell from the preinjection level of 612,000 per cubic millimeter to 96,000 in eight hours. The platelet count twenty-four hours after injection was 100,000 and rapidly rose to 605,000 in eight hours. It was again noted that bleeding was difficult to control when the platelet count was low, and again no purpuric areas were noted.

The commercial acetone that had been put on the spleen when the first reagent acetone was filtered off was now filtered and distilled, forming extract S-1-B. On September 14, 20 cc. of this extract was injected into a rabbit. The platelet count fell from 620,000 per cubic millimeter to 580,000 in six hours and rapidly rose to normal. This lack of potency might have been due to the use of commercial acetone instead of reagent acetone but was probably due to the fact that virtually all the platelet-reducing substance had been extracted by the first treatment with acetone.

The extract from the second spleen was prepared by a method identical with that used in the first case. The spleen was ground up in a food chopper imme-

diately after operative removal on June 28 and placed in reagent acetone. The acetone was distilled off on October 8, and 100 cc. of distilled water was added. This extract, S-2, also was always kept in the ice box.

On October 12, 20 cc. of this extract was injected into the marginal vein of the ear of a rabbit weighing 2.1 Kg. The platelet count fell from the preinjection level of 640,000 per cubic millimeter to 70,000 in twenty-four hours and rose to the preinjection level by the end of thirty-six hours (chart 1). In order to determine the minimal effective dose of the extract, 3 cc. was injected into a rabbit weighing 2.1 Kg. on October 18. The platelet count fell from a preinjection level of 640,000 to 80,000 in twenty-four hours and rose to normal in thirty-two hours (chart 2). A smaller dose had little effect on the platelet count.

On October 25, 5 cc. of the extract S-2 was injected into the marginal vein of the ear of a rabbit weighing 1.9 Kg. after control studies had shown the platelet count to be 580,000 per cubic millimeter, the red count 4,750,000, the white cell count 6,000 and the bleeding time two minutes. The platelet count fell to 70,000 in ten hours, but the red and white cell counts showed no appreciable change. The bleeding time, however, increased to four and one-half minutes. The platelet count was kept low for nine days, three additional injections of the extract being made when the count began to rise (chart 3). When the platelet count was low, around 70,000 per cubic millimeter, further studies showed the clotting time to be eight minutes and clot retraction not complete until twenty-four hours. The fragility of the red cells was within normal range.

In order to obtain further knowledge of the characteristics of the extract, 8 cc. was boiled for three minutes and then injected into a rabbit weighing 2 Kg. The platelet count fell from a preinjection level of 580,000 per cubic millimeter to 147,000 in twelve hours and rose again to normal in thirty-six hours. This test would seem to indicate that the substance producing thrombocytopenia is partly thermostable and would suggest in addition that its nature is possibly that of a protein.

Chart 4.—The changes in the number of platelets in the circulating blood of a cat, a dog and a monkey after the intravenous injection of a splenic extract obtained from a patient with idiopathic thrombocytopenic purpura.

Since the rabbit had been the test animal so far, it was decided to check these results on other laboratory animals. Accordingly, on November 16, 5 cc. of the extract S-2 was injected into the left external jugular vein of a cat weighing 3.2 Kg. The platelet count fell from a control level of 350,000 per cubic millimeter to 120,000 in twenty-four hours and then rapidly rose to normal in six hours. On the same day 5 cc. of the extract was injected intravenously into a dog weighing 7.2 Kg. The platelet count fell from a preinjection level of 310,000 to 110,000 in twenty-four hours and rose again to normal in seven hours. On November 19, 10 cc. of the extract was injected intravenously into a

monkey weighing 8.8 Kg. The platelet count again fell from a control level of 300,000 per cubic millimeter to 120,000 in twenty-four hours and then returned to normal in five hours (chart 4).

On Jan. 25, 1938, 3 cc., which represented the last of extract S-2, was injected into a rabbit, and a platelet count was made at hourly intervals. The control count was 580,000; the lowest count was 100,000, at fourteen hours, and the normal level was attained in twenty-four hours (chart 4). The fact that the platelet count did not fall so rapidly and did not remain low for a longer time might well be explained by the age of the extract.

On Oct. 18, 1937, patient E. K. entered the hospital for splenectomy to be performed on the following day. One hour before he went to the operating room 20 cc. of his blood was taken and immediately injected into the aural vein of a rabbit, but there was no fall in the platelet count of the animal's blood. The animal was found dead at the end of eight hours.

CASE 3.—E. K., a white youth, aged 19, was admitted to the Johns Hopkins Hospital on Oct. 18, 1937, with the complaint of excessive bleeding. The family history showed no excessive bleeding or blood dyscrasia. He was first seen in the Harriet Lane Home in 1925, when 7 years old, suffering from nephritis following pneumonia. On Aug. 19, 1925, he complained of severe abdominal pain and vomited blood. A diagnosis of Henoch's purpura was made. On October 25 he was again seen because he had been bleeding for two weeks from a bruised finger. A blood smear showed virtually no platelets. When

Chart 5.—The negligible changes in the number of platelets in the circulating blood of a rabbit after the intravenous injection of three representative control extracts.

6 years of age he bruised himself in a fall, and after that time he noted that he always bruised easily. Circumcision was performed when he was 13, with profuse hemorrhage for two days. On Nov. 7, 1935, he came to the hospital complaining of bleeding gums. Blood studies showed red cells 4,890,000 per cubic millimeter, hemoglobin content 15 Gm., bleeding time four minutes and clotting time eight minutes. The tourniquet test gave a positive reaction, and platelets were scarce. On July 8, 1936, he again returned to the dispensary complaining of bleeding gums. From July 14 to December 30 a series of fifteen injections of moccasin snake venom was given. During this period there was no spontaneous hemorrhage but the number of platelets remained low, from 22,000 to 70,000 per cubic millimeter, and the bleeding time remained about fifteen minutes. He began, however, to bruise easily again about Jan. 6, 1937, and seven roentgen treatments, directed primarily at the spleen, were given in three weeks, but to no avail. Blood studies on October 18 showed the platelet count to be 38,000 and the bleeding time to be ten minutes. A splenectomy was performed on October 19 by Dr. P. A. Kunkel, and blood studies on the following day showed the platelet count to be 84,600, bleeding time one and one-half minutes, clotting time four minutes and clot retraction time one hour. The platelets rose steadily to 810,000 by November 3. On November 5 the patient was admitted to the hospital with the complaint of pain in the left costovertebral angle, and a provisional diagnosis of an embolus to a radicle of the left renal artery was made. He was discharged asymptomatic on November 14. There was no return of bleeding, and on November 17 the platelets numbered 470,000.

The spleen weighed 127 Gm. and was small, smooth and glistening. Microscopic examination revealed a large number of splenic corpuscles, some of them having

germinal centers. Many sinuses were dilated. The pulp appeared normal, and there was no increase in cellular elements. The arterioles of the corpuscles were extremely sclerotic.

The extract from this spleen was prepared by a method identical with that in the two preceding cases. The spleen was ground up immediately after its surgical removal, on October 19, and put in 255 cc. of reagent acetone. The acetone was filtered and then distilled off on October 25, and 100 cc. of distilled water was added to the remaining extract. This extract also was always kept in the ice box, and it was known as S-3.

On October 27, after control counts had been made, 20 cc. of this extract was injected into the marginal vein of the ear of a rabbit weighing 2 Kg. The platelet count fell from 605,000 per cubic millimeter to 100,000 in twenty-four hours and then rose to 605,600 in an additional twenty-four hours. The red and white cell counts remained unchanged, but the bleeding time rose from a control of two and one-half minutes to four and one-half minutes when the platelets were at their lowest level. This extract seemed somewhat less potent than the two preceding extracts, as the injection of 5 cc. into a rabbit on November 22 caused a platelet drop from 600,000 only to 340,000 per cubic millimeter.

On November 25 an attempt was made to see whether massive doses of the extract would remove still more platelets from the blood; accordingly, 40 cc. of the extract was injected into a rabbit weighing 2.2 Kg. and having a platelet count of 602,000. The platelets, however, reached their lowest level at 100,000 per cubic millimeter, after six hours, and returned to normal values in thirty hours.

As soon as the first spleen extract showed an ability to reduce the number of platelets, control tissue was looked for, and curiously enough the most desirable tissue, a normal spleen, was the last specimen to be obtained. The experiences with the control series are chronologically arranged.

The first control extract was prepared from one lobe (weight 110 Gm.) of a thyroid gland removed for hyperthyroidism. The gland was removed on July 28, 1937, and was immediately ground up and put in acetone. The acetone was distilled off and distilled water added to the residue on August 20. On August 30, 20 cc. of the extract known as S-6 was injected into a rabbit weighing 2 Kg. The platelet count fell from 560,000 per cubic millimeter to 540,000, a change scarcely outside the range of experimental error.

The second control extract was prepared from a myomatous uterus weighing 500 Gm. The specimen was removed at operation on July 29, 1937, and the usual preparation was carried out, the acetone being distilled off on August 11. Twenty cc. of this extract, known as S-5, was injected into the vein of the ear of a rabbit weighing 2.2 Kg. on August 23. The platelet count fell from a preinjection level of 600,000 to 580,000 in four hours and had regained normal limits within another four hours (chart 5).

The third control extract was prepared from one half of the spleen removed from a patient having Banti's disease. The spleen was removed on October 19, prepared and put in acetone in the usual manner, and the acetone was distilled off on October 27. Twenty cc. of this extract injected into a rabbit on November 12 caused a fall in the platelet count from 580,000 per cubic millimeter to 550,000 in four hours, with a rise to 581,000 in an additional four hours (chart 5).

The fourth control extract was prepared from the spleen of a patient suffering from congenital hemolytic jaundice. The specimen was obtained at operation on July 27, 1937, and prepared by the usual method, the acetone being distilled off on October 19. The injection of 20 cc. of this extract into a rabbit on November 12 caused a fall in the platelet count from 588,000 to 570,000 per cubic millimeter in two hours, with a return to the preinjection level in six hours.

The fifth control extract was prepared from one half of the spleen of a patient who died of cardiac failure. The specimen, weighing 76 Gm., was obtained ten hours after death and was prepared in the usual manner. The spleen was obtained on Dec. 9, 1937, and the acetone distilled off on December 20. The injection of 20 cc. of this extract into a rabbit on December 27 caused a fall in the platelet count from 587,000 to 540,000 in four hours, with a rise to normal in eight hours.

The sixth control extract was prepared from a spleen removed because of a stab wound. The specimen was obtained at operation on March 5, 1938, and prepared in the routine manner. The acetone was distilled off on March 30. The injection of 20 cc. of this extract into a rabbit on April 12 caused a fall in the platelet count from 640,000 to 610,000 per cubic millimeter in four hours, with a return to the preinjection level in eight hours (chart 5).

COMMENT

Although extracts were made from only three spleens, the results were so uniform that it was felt justifiable to publish these observations before waiting for more material. The three cases were obviously of idiopathic thrombocytopenic purpura.

For the sake primarily of convenience it is suggested that the substance which has thus been found in the extracts of spleens taken from patients suffering from idiopathic thrombocytopenic purpura and which reduces markedly the number of platelets in the circulating blood of a rabbit after intravenous injection be called thrombocytopen, and this new term will therefore be used in the remainder of the article.

Simple as it was, the preparation of the extracts was nevertheless entirely empiric. Previous work in the preparation of intermedin from the hypophysis of cattle² showed that the acetone functioned primarily as a preservative and that the active principle was taken out by dilute acetic acid. In the case of the spleen, however, it was acetone that took out the substance that reduced the number of platelets. Whether it is essential to use reagent acetone rather than the commercial variety is open to question. It is probable that the commercial variety will prove to be satisfactory, but only parallel tests can establish this point. Furthermore, whether acetone and not alcohol, ether, water or dilute acetic acid is the best extracting substance remains to be determined.

The correct length of time to allow for the extraction of thrombocytopen by the acetone is still to be established. In the first case this period was sixty-seven days, in the second case one hundred and two days and in the third case six days. The third spleen gave the weakest extract, but it was from a patient who had received roentgen radiation over the splenic area. Thus, radiation brings in another unknown quantity.

Still another factor in the potency of the extracts is the weight of the spleen. Obviously, a large spleen

should yield more thrombocytopen than a smaller one. The weight of the three spleens, however, was so nearly the same that the difference in potency of the extracts from the second and third spleens cannot be explained on this basis.

It is possible that thrombocytopen may be found in other organs besides the spleen, and it is thus understandable why the spleen from some patients may not have as heavy a concentration of this substance as the spleen of others and why failures after splenectomy have occurred. The extrasplenic tissue which naturally suggests itself in this connection is the reticulo-endothelial system, for Kaznelson³ pointed out that the spleen is only a part of the reticulo-endothelial system, and other parts of this system might be primarily affected. Other possible explanations for failures after splenectomy are the presence of accessory spleens (Morrison, Lederer and Fradkin⁴) and the fact that many spleens are removed because of a mistaken diagnosis (Koster⁵).

The theory that the spleen in cases of thrombocytopenic purpura produces a toxin is not a new one. In 1915 Frank⁶ advanced the idea that this organ produces a noxious substance that causes thrombopenia by inhibition or destruction of the megakaryocytes of the bone marrow. This theory has been the most widely accepted one. Minot⁷ in 1917 modified it by suggesting that the deleterious agent can act on the circulating platelets, on the megakaryocytes or on the marrow as a whole. In spite of the relatively long time that this idea of a splenogenous toxin has been current, remarkably few attempts to isolate the toxin have been made. Torrioli and Puddu⁸ observed a substance in the spleen of patients with purpura that was toxic to tissue cultures of megakaryocytes. This substance was also seen in other organs and appeared to be related to the presence of reticulo-endothelial tissue in the organs. Attempts have been made more toward understanding purpura itself than toward isolating a cause of idiopathic thrombocytopenic purpura. The work with antiplatelet serum, as begun by Marino⁹ in 1905 and Cole¹⁰ in 1907 and more recently carried on by Tocantins,¹¹ Jones,¹² Lee and Robertson,¹³ Watabiki,¹⁴ Bedson¹⁵ and others has greatly advanced the knowledge of purpura itself.

The character of the curve in chart 1 and to a less extent of that in chart 3, showing a sharp fall in the number of platelets and then twenty-four hours later an even sharper rise, brings up the question as to the mode of action of thrombocytopen. More noteworthy

moderate, from twenty-one to forty organisms engulfed; marked, over forty organisms engulfed.

In March 1937 we had an opportunity to determine the opsonocytaphagic activity of a patient suspected of having brucellosis. A brief history is given:

CASE 1.—J. K., a woman aged 30, complained of generalized muscle pains, chills, fever, nausea and vomiting for two weeks. On physical examination the temperature was 103 F. and the pulse rate 104. The patient was slightly irrational. There were ecchymotic blotches over the extremities and hyperesthesia over the entire body. The course was acutely febrile for three weeks with leukocytosis. Toxic effects on the liver and kidneys were evidenced by bile, albumin three plus and casts in the urine. Agglutination tests for typhoid, paratyphoid and *Brucella* were negative March 22, 25 and 29. Sulfanilamide, 90 grains (6 Gm.), was given on March 26, 27 and 28 and then stopped. Opsonocytaphagic activity on March 30 was 95 per cent marked phagocytosis. Opsonocytaphagic activity one week later was

of the five cases reported three showed no agglutination with *Brucella* before sulfanilamide therapy but acquired agglutinins after this drug was administered. A fourth case presented a positive agglutination before the drug was given. In the fifth case no test for agglutinins was made after treatment.

CASE 2.—A. B., aged 33, seen Aug. 18, 1937, had vague complaints for three weeks with high fever and indefinite abdominal pain. On physical examination the temperature was 104.8 F., the pulse rate 92 and the respiratory rate 24. The throat was slightly injected, with no cervical glands; the liver and spleen were slightly palpable. The chest was clear on physical and x-ray examination. Agglutination tests for typhoid and undulant fever were negative. The urine and stools were normal. The Kahn reaction, the blood picture and the Widal reaction were all negative. Treatment consisted of sulfanilamide begun August 18 (90 grains a day for five days, increased to 120 grains [8 Gm.] for five days, then decreased to 60 grains [4 Gm.] for

* Huddleson method.

† Treatment 10 grains over a period of two days (5 grains a day). Index determined forty-eight hours after last injection of drug.

10 per cent marked phagocytosis. *Brucella* agglutination was found positive April 13. Opsonocytaphagic activity April 13 was 58 per cent marked phagocytosis. April 13 the temperature was normal. The patient was released from the hospital April 22. There was no return of symptoms.

In view of Huddleson's classification of susceptible, infected and immune persons on the basis of their opsonocytaphagic activity, an index of 95 per cent marked phagocytosis as shown by patient 1 while extremely ill was not expected. The index of 10 per cent marked phagocytosis demonstrated forty-eight hours after sulfanilamide therapy was stopped appeared to be more in line with the patient's condition.

It seemed desirable to determine in other cases of brucellosis the opsonocytaphagic activity before and after sulfanilamide therapy. Brief histories of four such cases are given. A marked increase in phagocytic activity occurred following administration of sulfanilamide. Two cases showed an increase of from 8 to 80 per cent marked phagocytosis and from 0 to 92 per cent marked phagocytosis, and two cases showed an increase from 0 to 28 per cent and from 0 to 30 per cent marked phagocytosis. It is of interest to note that

three days). Opsonocytaphagic activity August 18 was 47 per cent no phagocytosis, 50 per cent slight, 3 per cent moderate and 0 marked. Following sulfanilamide August 24 opsonocytaphagic activity was 8 per cent no phagocytosis, 40 per cent slight, 22 per cent moderate and 30 per cent marked. Typhoid vaccine was given intravenously in three small doses August 20, 21 and 22. The patient's temperature fell to normal September 4 and except for two slight rises has remained normal. September 7 the opsonocytaphagic activity was 0 negative, 8 per cent slight, 18 per cent moderate and 74 per cent marked phagocytosis.

CASE 3.—O. M. S., a man aged 55, complained of onset of fever Sept. 13, 1937, rising in one week to 104 F. The agglutination test for undulant fever was negative. The skin test was moderately positive. The opsonocytaphagic index showed the patient to be in the infected group: 46 per cent no phagocytosis, 46 per cent slight, 8 per cent moderate, 0 marked. Agglutinins for typhoid and paratyphoid were negative. Physical examination was negative except for fever, low blood pressure and tenderness of the lower part of the legs. Sulfanilamide was started on the eleventh day (120 grains the first week). Opsonocytaphagic activity one week after sulfanilamide therapy was started showed 92 per cent marked phagocytosis with 8 per cent moderate. Five days after sulfanilamide was stopped this dropped to 14 per cent marked

phagocytosis with no phagocytosis in 15 per cent. The agglutination test for *Brucella* was positive up to 1:320 on November 15. The temperature fell to normal on the second day of treatment and has remained there.

CASE 4.—M. S., a woman aged 66, with onset of fever Oct. 20, 1937, complained of drowsiness, fatigue, malaise for the preceding six weeks and afternoon temperature up to 100.6 F. for the past ten days. General physical examination and routine laboratory examinations were negative. The agglutination test for undulant fever was negative, but the cutaneous

days, malaise, chills and headache. Physical examination was negative except for the fever. Agglutination and cutaneous tests were both strongly positive June 15. Opsonocytophagic activity June 16 was 12 per cent no phagocytosis, 38 per cent slight, 44 per cent moderate and 6 per cent marked. Sulfanilamide was started (June 18) (only 60 grains was given). Therapeutic brucellin 0.1 mg. intracutaneously June 19 gave a severe reaction and was stopped. Opsonocytophagic activity June 22 was 20 per cent moderate and 80 per cent marked phagocytosis. Opsonocytophagic activity June 25 was 11 per cent no phago-

* In these two counts 4 per cent of the cells showed moderate phagocytosis, but in no other instance was more than slight engulfment shown.

test was strongly positive. Opsonocytophagic activity November 5 was 100 per cent no phagocytosis. After an irregular fever for three weeks the patient was given sulfanilamide (300 grains in one week). Opsonocytophagic activity then showed 28 per cent marked and only 2 per cent no phagocytosis. The temperature, which had been normal after the first day of sulfanilamide, returned and another course of sulfanilamide was given (100 grains [6.5 Gm.] a day for five days). The opsonocytophagic activity was then found to be 28 per cent marked and 0 no phagocytosis. A second agglutination test was positive up to 1:160. The patient had fever altogether for approximately forty days with remissions during sulfanilamide therapy. She was given a total of 300 grains (20 Gm.) during the first course and 500 grains (32 Gm.) during the second. There has been no return of symptoms.

CASE 5.—F. B., a farmer aged 54, seen June 14, 1937, had many cows that had aborted. He complained of fever for nine

cytosis, 29 per cent slight, 40 per cent moderate and 20 per cent marked phagocytosis. The patient was discharged June 26 with a normal temperature.

To determine whether sulfanilamide therapy in other infections stimulates an increase in opsonocytophagic activity toward *Brucella*, five patients with gonorrhea and one patient with relapsing fever were each given a total of 300 grains (20 Gm.) of sulfanilamide over a period of five days. The opsonocytophagic activity was determined before and after administration of the drug. No appreciable change occurred in the opsonocytophagic activity toward *Brucella* after sulfanilamide therapy.

In the control gonorrhea group the opsonic activity of the blood of these patients was also tested again: *Neisseria gonorrhoeae*, *Monilia candida*, *staphylococci*, *Eberthella typhosa*, *Escherichia coli*, *pneumococci* type

I, III and VIII and, in some instances, beta hemolytic streptococci. A definite increase in opsonic activity was demonstrated for both hemolytic streptococci and staphylococci but no appreciable change could be shown with any of the other organisms listed.

ANIMAL EXPERIMENTS

Eleven guinea pigs were injected each with 100 million live *Brucella abortus* organisms suspended in

Fig. 1 (guinea pig 162).—Opsonocytophagic index before sulfanilamide treatment.

saline solution. On the twentieth day after injection an opsonocytophagic index was determined on each animal and on four normal controls. Six of the infected guinea pigs and the four normal guinea pigs were then injected subcutaneously with 5 grains (0.3 Gm.) of sulfanilamide suspended in olive oil. Twenty-four hours later a similar injection was made (total 10 grains [0.6 Gm.]). Forty-eight hours after the last injection of sulfanilamide opsonocytophagic tests were made on all guinea pigs comprising five⁸ infected treated, four uninfected treated and five infected untreated. The results are given in table 1.

All the infected animals treated with sulfanilamide showed marked increases in phagocytic activity. The average percentage of cells showing marked phagocytosis before treatment was 20 per cent and after treatment 97 per cent.

In the infected untreated group of animals the average percentage of cells showing marked phagocytosis on the twentieth day after injection was 35 and on the twenty-third day only 43. The uninfected treated guinea pigs showed no change in phagocytic activity.

An average increase in opsonic activity from 20 to 97 per cent of marked phagocytosis in *Brucella* infected guinea pigs following treatment with sulfanilamide is a significant one. It was felt, however, that an even greater difference might be demonstrated if sulfanilamide therapy was started earlier in the process of infection.

A series of seventeen guinea pigs was injected intraperitoneally with *Brucella abortus* in a dose of 100 million. Ten days after injection an opsonic index for *Brucella* was done on each animal and 5 grains of sulf-

anilamide in olive oil was injected subcutaneously into ten of the infected guinea pigs, seven being withheld as untreated controls. Four normal guinea pigs were each given 5 grains of sulfanilamide at the same time the infected animals were treated. On the following day a further dose of 5 grains of sulfanilamide in olive oil was injected subcutaneously into both the infected and the uninfected group. Forty-eight hours later a second opsonic index was determined on all guinea pigs. The results obtained are shown in table 2.

The change in the degree of phagocytosis in infected guinea pigs following treatment with sulfanilamide was even greater than in the first series (table 1). Four guinea pigs in the infected treated group (152, 162, 309 and 189, table 2) which had shown 100 per cent negative phagocytosis before treatment with sulfanilamide showed 100 per cent marked phagocytosis after treatment.

Figures 1 and 2 are reproductions of photomicrographs of typical fields observed (guinea pig 162) before and after treatment with sulfanilamide. Figure 3 shows the opsonocytophagic activity of the blood of guinea pig 309 after treatment with sulfanilamide. Before sulfanilamide treatment the leukocytes show no engulfment and the *Brucella* organisms are evenly distributed throughout the field. After treatment not only is there marked engulfment but there appears to be a positive chemotaxis of the organisms for the white cells. This phenomenon has been noted throughout these studies with *Brucella* organisms.

Five guinea pigs in the control (infected untreated) group died between the tenth and the thirteenth day of the experiment (table 2). In the treated uninfected group no change in opsonic index was observed.

In order to determine whether sulfanilamide was present in the blood of infected guinea pigs at the

Fig. 2 (guinea pig 162).—Opsonocytophagic index after sulfanilamide treatment.

time that marked phagocytic activity was demonstrated, the blood serums of all treated animals were tested for sulfanilamide. In the first group tested (table 1) none of the infected treated animals showed sulfanilamide in their blood serum, while those which were not infected but treated simultaneously with the same amount of sulfanilamide as the test group all showed

8. One infected animal in this group died before treatment.

some sulfanilamide present. In the second series the results were not as uniform although of the ten infected treated animals seven showed no sulfanilamide in their blood while in the control group of four animals two showed sulfanilamide in the blood.

Since serums from the first group of guinea pigs (table 1) showed no sulfanilamide and the blood of these animals was extremely active against *Brucella* organisms, it seemed advisable to determine whether the cells or the serum of such infected treated animals was the active agent in bringing about marked phagocytosis. Accordingly, in all five guinea pigs of the infected treated group (table 1) blood was withdrawn from the heart into citrate solution (final concentration 0.78 per cent) and the serum removed by centrifugation. The cells were washed twice with salt solution (0.85 per cent).

Opsonocytophagic tests were then done after serums of infected treated guinea pigs were combined with the cells of normal guinea pigs and with the cells of uninfected treated guinea pigs. Tests were also made

Fig. 3 (guinea pig 309).—Opsonocytophagic index after sulfanilamide treatment.

with the cells of the infected treated guinea pigs suspended in the serums of normal guinea pigs and with these cells in the serums of uninfected treated guinea pigs. In each case 0.1 cc. of cells, 0.1 cc. of serum and 0.1 cc. of a *Brucella abortus* suspension were mixed in agglutination tubes and incubated in the water bath at 37 C. for one-half hour. Blood smears were made in the usual way and stained with Hastings' stain and the degrees of phagocytic activity determined. The results obtained are given in table 3.

The serum of an infected treated guinea pig is capable of stimulating the cells of both normal guinea pigs and of treated uninfected guinea pigs to the same degree of phagocytosis that it stimulated its homologous cells. When normal human cells were suspended in serums of infected treated guinea pigs a similar stimulation of phagocytosis occurred. On the other hand the cells of infected treated pigs in the presence of normal serum or serum from treated uninfected guinea pigs completely lost their phagocytic activity.

An attempt was made to sensitize cultures of *Brucella* by treatment with sulfanilamide in vitro. Cultures so

treated were not engulfed by either normal human or normal guinea pig cells. Conversely, treatment of normal guinea pig or normal human blood in vitro failed to increase opsonic activity against untreated *Brucella* or against *Brucella* treated as described.

These results show that the activity evidenced in the serums of sulfanilamide-treated infected guinea pigs, but not in the leukocytes, is not the result of the presence of free sulfanilamide. These studies, however, suggest that the activity results in a stimulation of opsonins as the direct or indirect effect of the treatment on the infected animal.

To determine the specificity of the active agent, the blood of guinea pigs infected with *Brucella* and of patients with brucellosis has been tested against other organisms. Guinea pigs infected with *Brucella* and treated with sulfanilamide show a marked increase in opsonic activity for *Brucella*, but only slight changes in opsonocytophagic power could be demonstrated for *Shigella paradysenteriae* Sonne and Harris, *Shigella alkalescens* and *Eberthella typhosa*.

The blood of patients with brucellosis, although showing marked opsonocytophagic activity against *Brucella* following sulfanilamide therapy, showed no appreciable change in opsonic activity against *E. typhosa*, *Salmonella schottmülleri*, *Shigella alkalescens*, *Monilia*, *Salmonella supestifer* or *Escherichia coli*. However, a marked increase in phagocytic activity was shown with hemolytic streptococci and staphylococci.

It should be stressed that both normal persons and normal guinea pigs treated with sulfanilamide show no increase in their opsonocytophagic activity for *Brucella* or for any of the other organisms tested, with the exception of the activity in human beings for hemolytic streptococci and staphylococci.

COMMENT

It has been estimated that from 5 to 15 per cent of true cases of undulant fever fail to show agglutinins. In our experience the intracutaneous test may be positive in uninfected persons and the opsonocytophagic test may show a positive result in uninfected persons and, vice versa, absence of phagocytic activity in infected persons.

The investigations by Baumgartner, Robinson and Evans⁹ of the opsonocytophagic test as a means of determining *Brucella* infection indicate that it may be difficult to interpret even when both the cutaneous reaction and results of agglutination are known. Our studies indicate that in persons infected with *Brucella* the use of sulfanilamide therapy markedly stimulates the phagocytic activity of the white blood cells for *Brucella*. Since sulfanilamide-treated normal persons and persons with other infections show no change in opsonocytophagic activity for *Brucella* organisms, it appears that the use of this drug in suspected cases of brucellosis should be a helpful diagnostic procedure. The results obtained in infected sulfanilamide-treated guinea pigs were similar to those demonstrated in human beings. Berger and Schnetz¹⁰ recently reported the successful treatment in a case of undulant fever with prontosil. Our results in a series of five cases of brucellosis indicate that sulfanilamide may be a valuable therapeutic aid in the treatment of this disease.

9. Baumgartner, L.; Robinson, F., and Evans, A.: An Evaluation of the Opsonocytophagic Activity Test in the Diagnosis of *Brucella* Infections, reported at the American Public Health Association Meeting, New York in October 1932.
10. Berger, W., and Schnetz, H.: Success of Treatment with Prontosil in a Case of Bang's Disease, *Med. Klin.* 23: 594 (April 30) 1932.

The investigations of Long and Bliss indicate that sulfanilamide acts *in vivo* by bringing about a change in the susceptible micro-organisms which permits phagocytosis. In a recent article Osgood and Brownlee¹¹ note that the major action of sulfanilamide on beta hemolytic streptococci seems to be neutralization of the toxins and that the drug has no direct effect on phagocytosis. The latter authors used *in vitro* experiments with cultures of human marrow to support their contentions, whereas Long and Bliss came to their conclusions following *in vivo* experiments in mice.

Our studies show that in cases of human brucellosis and in guinea pigs infected with *Brucella abortus*, treatment with sulfanilamide markedly increases phagocytosis. Individuals infected with other diseases and normal guinea pigs treated with sulfanilamide show no change in their opsonocytophagic activity for *Brucella abortus*. Further, the blood of normal human beings or normal guinea pigs, even when treated *in vitro* with sulfanilamide, shows no change in opsonocytophagic activity when mixed with untreated *Brucella abortus* or with sulfanilamide-treated organisms.

It has been possible in infected guinea pigs treated with sulfanilamide to demonstrate absence of the drug in the blood at the time at which marked phagocytosis occurs and, further, to transfer this marked phagocytic activity to normal guinea pig and human cells by suspending them in the serum of infected treated guinea pigs. Since the presence of sulfanilamide as such is not essential for the demonstration of marked phagocytosis in infected treated guinea pigs, it would appear that the effect of the drug is an indirect one. Osgood and Brownlee's demonstration of destruction of the erythroxin of beta hemolytic streptococci with sulfanilamide would indicate that at least with this organism one of the mechanisms of its action is the destruction of such exotoxins. On the other hand, with *Brucella abortus*, which produces no exotoxin, some other explanation for the action of the drug on this organism is necessary. It is well known that *Brucella* filtrates are extremely toxic and produce in infected and sensitized individuals marked reaction when injected intracutaneously in small amounts. The toxicity of such filtrates are manifested not only by local reactions but also by definite systemic reactions such as malaise, high fever and headache. It appears to us that sulfanilamide acts indirectly in *Brucella* infections by increasing the opsonic power of the blood and thus neutralizing the effect of the endotoxin or aggressin-like substances produced by this organism allowing phagocytosis to take place. The fact that it was not possible to stimulate the opsonic power of the blood toward *Brucella* of uninfected human beings or guinea pigs by treatment with sulfanilamide would indicate that an infective or immunizing process must be in progress for the drug to stimulate phagocytosis in this disease. However, an active infective process with beta hemolytic streptococci or staphylococci does not appear to be necessary for the drug to stimulate phagocytosis of these organisms. In normal or in infected human beings treated with sulfanilamide the opsonocytophagic power of the blood was increased markedly for the latter organisms. An explanation of the phagocytic activity induced by sulfanilamide therapy in human beings against beta hemolytic streptococci and staphylococci may lie in the wide distribution of these organ-

isms with correspondingly increased chances for previous infection or for partial immunization by subinfective doses. Experimental studies of this phase of the problem in animals are now in progress.

CONCLUSIONS

The use of sulfanilamide would appear to be a valuable aid in the diagnosis and treatment of human brucellosis.

Animal experimentation indicates that in *Brucella* infections sulfanilamide markedly increases opsonocytophagic activity for *Brucella* organisms.

In *Brucella* infections sulfanilamide appears to act through stimulation of the defense mechanism of infected animals by increasing the production of specific opsonins, thus affecting neutralization of the endotoxin or aggressin-like substances produced by these organisms, with resulting phagocytosis.

THE LATERAL PYELOGRAM AS A DIAGNOSTIC AID IN PERI- NEPHRIC ABSCESS

JOHN G. MENVILLE, M.D.

NEW ORLEANS

Perinephric abscess is an age old condition recognized as a clinical entity for many years, yet it remains undiagnosed in a large percentage of cases. In diagnosis this condition may be confused with traumatic rupture of the kidney, pyonephrosis, nephrolithiasis, renal or perirenal tumors, lumbar arthritis, lumbar hernia, retrocecal appendicitis, subdiaphragmatic abscess, gall-bladder disease, tuberculosis of the spine or hip, osteomyelitis of the ribs or a ruptured viscus. Consequently, any patient with a history of chills, fever or lumbar pain and presenting tenderness of the costomuscular angle, leukocytosis and rigidity of the lumbar and psoas muscles should undergo a complete urologic examination.

In 1921 Bela Alexander¹ of Leipzig reported two cases of perinephric abscess showing a disappearance of the psoas line and a poorly defined kidney outline on the affected side; in one of the cases there was a curvature of the spine and a retraction of the thigh. In 1928 Beer² and Lipsett³ independently and simultaneously brought out and stressed these signs in the diagnosis of perinephric abscess. In 1929 Peacock⁴ stressed the fact that a retrorenal or a retroperitoneal mass producing an anterior and a lateral displacement of the kidney and ureter could be demonstrated by stereoscopic roentgenograms. In his opinion, lateral roentgenograms would show the same displacement, but such a procedure offered too many difficulties. In 1934 Mertz and Hamer⁵ demonstrated the value of lateral pyelograms in urologic diagnosis, but in their series they made no mention of nor did they demon-

strate a perinephric abscess. Cabot⁶ stresses the importance of the limitation of movement of the inner portion of the diaphragm in large perinephric abscesses.

Failure to recognize the condition or to institute proper and early treatment is probably the explanation of the high mortality rates reported in the literature; therefore, any diagnostic procedure which facilitates an accurate diagnosis will help to lower these rates.

REPORT OF CASES

In four cases in which perinephric abscess was clinically suspected lateral pyelograms were made, and in the advanced cases the corresponding kidney and ureter were found to be markedly displaced anteriorly. Although lateral pyelograms have been used elsewhere in the diagnosis of various renal and retroperitoneal lesions, I⁷ am unable to find any reference of this procedure being used in perinephric abscess except in my preliminary report in 1937.

CASE 1.—A white youth aged 19 suffered from pain in the left lumbar region and from occasional chills and fever for fourteen months. Furuncles about the face appeared shortly after the onset of pain. Examination revealed that the patient was emaciated, with a limping gait, a slight curvature of the spine and a tendency to elevate the left thigh. There was pain on extension of the left thigh, rigidity of the left lumbar muscles, a deep-seated, firm, slightly tender mass in the region of the left kidney, a mild leukocytosis and a temperature of 99 F. The blood chemistry, the urine from the bladder and from each kidney, and the function of each kidney were normal.

A roentgenogram of the kidneys, ureters and bladder showed a curvature of the lumbar spine, with the concavity pointing to the left side and an obliteration of the shadow of the left psoas muscle. A left retrograde pyelogram, with anteroposterior and lateral views, showed an enlarged kidney with a compression of the upper calix and a marked anterior displacement of the kidney and ureter (fig. 1). Oct. 29, 1936, a left-sided perinephric

Fig. 1 (case 1).—A, a preoperative retrograde pyelogram of a patient with a perinephric abscess, showing the enlarged left kidney, with a slight blunting of the lower calices and a compression of the upper calix. The spine shows a curvature, with the concavity pointing to the left side. B, a lateral pyelogram made four months after operation, showing the kidney and ureter to be in normal position. (Compare with figure 1 A.)

abscess of *Staphylococcus albus* origin, containing approximately 1,500 cc. of thick purulent material, was drained. Four months after operation the patient returned for an examination at my request. A retrograde pyelogram with anteroposterior and lat-

eral views showed the pelvis and calices to be normal and the kidney and ureter to be in normal positions (fig. 2).

CASE 2.—A white man aged 27 suffered from pain in the right lumbar region and from chills and high fever for four months. There was a loss of 15 pounds (6.8 Kg.) and a limping gait increased frequency and nocturia. On examination the patient was weak and emaciated and had a temperature of 103 F., tenderness over both lumbar regions, a tender movable mass in the

Fig. 2 (case 1).—A, a retrograde pyelogram made four months after operation, showing the pelvis and calices to have returned to their normal size and shape. The spine has also returned to a normal straight line. (Compare with figure 1 A.) B, a lateral pyelogram made four months after operation, showing the kidney and ureter to be in normal position. (Compare with figure 1 B.)

right side, rigidity of the muscles of the right lumbar region and a slight flexion of the right thigh. A roentgenogram of the abdomen revealed a slight curvature of the lumbar spine, with the concavity pointing to the right side and an obliteration of the shadow of the right psoas muscle. A right-sided retrograde pyelogram revealed an overdistended pelvis with some pyelovenous backflow. A lateral view showed the kidney and ureter to be displaced anteriorly in a smooth, arclike manner.

April 12, 1937, a large right-sided perinephric abscess was drained. Twenty-one days later a right-sided retrograde pyelogram in the anteroposterior and lateral views revealed the kidney to be of normal size and in a normal position.

CASE 3.—A white man aged 33 suffered from cramping pains in the right side of the abdomen for seven days and in the right kidney for two days. A year previously an appendical abscess had been drained. Examination revealed spasticity of the right lumbar muscles with tenderness in that region and pain on extension of the right thigh. The urine was essentially normal. A leukocyte count of 12,350 was found. The urine specimen from each kidney as well as the function of each kidney was normal. A roentgenogram of the abdomen was obscured by gas shadows. Retrograde pyelograms in the anteroposterior position revealed an enlarged left kidney, low in position, and a right kidney with an incomplete filling of the lower calix. A lateral view showed the right kidney and ureter to be displaced anteriorly in a smooth, regular, arclike manner.

April 12, 1937, a large right-sided perinephric abscess of *Bacillus coli* origin was drained. Seventeen days later a right retrograde lateral pyelogram showed the kidney to be in a normal position, but the lower end of the ureter was still somewhat displaced anteriorly. This deformity was probably due to adhesions from the old appendical abscess.

CASE 4.—A white boy aged 4 years suffered from nausea and vomiting six days prior to admission. Following a purgative, pain developed in the lower right quadrant radiating to the right thigh and to the costal margins posteriorly. Examination revealed that the child was moderately ill, with a temperature

of 102 F., a marked tenderness in the right lumbar region and in the abdomen to the right of the umbilicus. The urine from the bladder and from each kidney was normal. Retrograde pyelograms revealed that the pelves and calices were normal. A lateral view of the right pyelogram showed that the kidney and ureter were displaced only slightly anteriorly and had no arclike curves. June 10, 1937, the kidney was explored and the lower pole was found to be inflamed, indurated and adhering to the retroperitoneum. About 3 cc. of purulent material was drained from the wound. A generalized peritonitis developed and the patient died eleven days after operation.

COMMENT

In the first case presented in this paper a lateral pyelogram was attempted in an effort to verify the diagnosis of perinephric abscess. The technic of having the patient lie on the affected side, perpendicular to the x-ray film, while the pyelogram was made, was so simple and so successful that the same procedure was carried out in the subsequent cases. However, the accuracy of a lateral pyelogram is dependent on the patient's lying perpendicular to the film, for if the side of the patient away from the film is tilted back the kidney nearest the film will normally cast a shadow anterior to the vertebral column.

The anterior displacement of the kidney and ureter in a smooth, regular, elongated arclike manner in patients with a large perinephric abscess is produced by the retroperitoneal accumulation of purulent material. A similar displacement by other forms of fluid is possible; I have seen such a condition following the extravasation of urine from a traumatic rupture of the kidney. Blood and chyle should act in a similar manner. In the absence of free fluid in the retroperitoneal space, I know of no condition that will produce a smooth anterior arclike deformity of the kidney and ureter with the exception of an aneurysm of the abdominal aorta.

In early cases of perinephric abscess in which only a few cubic centimeters of purulent material has accumulated, the displacement of the kidney and ureter may be so slight as to be scarcely noticeable. However, if there is sufficient infection to produce edema of the surrounding tissue, the kidney and possibly the ureter will be displaced anteriorly but not in an arclike fashion. The lateral pyelogram produces a typical deformity in advanced cases of perinephric abscess, while in the early cases the displacement is slight. Any displacement of the kidney anteriorly is suggestive of retroperitoneal disorder.

CONCLUSION

Lateral pyelograms in three cases of perinephric abscess presented a uniform, anterior, arclike displacement of the kidney and ureter on the affected side. Postoperative lateral pyelograms in the same cases showed the kidneys and ureters to be in normal positions with no evidence of anterior displacement. A lateral pyelogram in a very early case of perinephric abscess showed a minute anterior displacement of the kidney and ureter.

Maison Blanche Building.

Soil as Important as Seed.—But today we can recognize that bacteriology has not brought us all the gifts we anticipated. For it overlooked for a time that the soil was an important factor in infection as well as the seed. There is not only the microbe which invades the individual but there is the reaction of that individual to the microbe to be considered.—Langdon-Brown, Walter: *The Dead Hand in Medical Science*, *Lancet* 1:278 (Jan. 29) 1938.

FIBROUS AND FATTY REPLACEMENT OF RENAL PARENCHYMA

LOUIS J. ROTH, M.D.

AND

HORACE B. DAVIDSON, M.D.

COLUMBUS, OHIO

Replacement of renal parenchyma by fatty tissue has been until recently regarded as a rare condition, as a specific type of process resulting from infection and as limited almost entirely to the so-called surgical diseases of the kidney. Mention of this disease in the literature has been infrequent, and the confusion as to its cause is indicated by the profusion of titles given it. These include fatty transformation of the kidney, fatty degeneration of the kidney, lipomatosis renis, substitutio renis adiposa, lipomatous paranephritis, lipoma-

Fig. 1 (case 1).—Nephrolithiasis, grade 4 replacement; sudan IV.

tous nephritis, lipome intranephritic and degeneration lipoma. The main purpose of this paper is at once to clarify, simplify and enlarge the concept of this particular entity.

In the early literature replacement lipomatosis was at times confused with true lipoma of the kidney, a condition which is quite rare. Elansky¹ quoted Lubarsch as saying that in 40,000 autopsies only one lipoma was observed in the kidney. Moreover, a true lipoma of the kidney is usually small, encapsulated, located directly beneath the capsule of the kidney and surrounded by normal renal tissue. Replacement lipomatosis is not found in a normal kidney, being an invasive proliferation of fat extending from the hilus and the pelvis toward the periphery of the kidney as a replacement process supplanting destroyed or atrophied parenchyma.

From the Departments of Urology and Pathology of St. Francis Hospital and the Ohio State University College of Medicine.

Dr. W. N. Taylor, head of the Department of Urology of the Ohio State University College of Medicine, allowed us to include two of his cases in this report.

1. Elansky, N. N.: *Lipomatosis Perirenalis cum Atrophia et Substitutione Adiposa Renis*, *Ztschr. f. urol. Chir.* 26: 431-446, 1929.

There are at present two main theories as to the cause and the nature of this fatty replacement of renal parenchyma: 1. Chronic inflammatory processes in the kidney stimulate hyperplasia of the perirenal and peripelvic fat, which then enter the kidney through the capsule or hilus by active invasion, producing atrophy of renal parenchyma. Von Rokitsansky,² Israel³ and Matsuoka⁴ advocate this theory. 2. Atrophy of the kidney due to some destructive process is the primary factor and is followed by secondary invasion on the part of the proliferating fat. The majority of investigators, including Borst,⁵ Gimpelson,⁶ Elansky,¹ Bacon and LeCount,⁷ Kutzmann⁸ and Krymholz,⁹ favor this theory, whereas a minority hold to the first hypothesis.

In regard to these varying concepts of the cause, it is noteworthy that the kidney retains its integrity despite pressure brought to bear by a retroperitoneal tumor or other large intra-abdominal mass. This fact does not tend to substantiate the theory of atrophy produced by pressure from proliferation of fat. It has been agreed by practically all investigators up to this time that the condition as a whole is due to some slow inflammatory process. Kutzmann⁸ has stated that calculous disease is the primary and initial factor, which leads to infection and destruction of kidney tissue with resulting pyonephrosis. Borst⁵ expressed the opinion that a proliferation of fatty tissue, such as compensates for the defect produced by muscular atrophy in certain types of muscular dystrophy, is active here also. Gimpelson⁶ stated that this phenomenon belongs to the classification hyperplasia ex vacuo: substitution of fat for destroyed parenchyma. This process can be considered biologically as an attempt of the organism to maintain its equilibrium.

lipomatosis. Previous to 1900 the condition had been seen only at autopsy; Israel³ in 1901 was the first to report it postoperatively. In 1931 an excellent review of the literature was made by Kutzmann,⁸ who collected thirty-two cases and added one of his own. Of these thirty-two cases, twenty-eight were reported from foreign sources. Since 1931 eighteen additional cases have been recorded in the American literature: eleven by Young,¹² two by Culver,¹³ and one each by White and Cambridge,¹⁴ Exley and Devereaux,¹⁵ Kretschmer and Pierson,¹⁶ Peacock and Balle¹⁷ and Wethall. Krymholz in 1932 added two cases of his own to twelve cases which he collected, two of which had been mentioned previously by Kutzmann; he also reported that Tjurkoff had collected seven cases, two of which also were mentioned by Kutzmann. Since the report of Krymholz one case each has been recorded by Scandurra¹⁸ and Gridnev,¹⁹ making a total of seventy reported cases.

Kutzmann reported that stone was found in 79 per cent of his collected cases. In the total seventy reported cases the frequency of stone was 76 per cent. Lipomatosis usually occurs unilaterally, favoring neither the right nor the left kidney, though Richards²⁰ and Grifon²¹ reported cases of bilateral involvement. The age of the patient varied from 10 years, in Browne's²² case, to 77, the age of Peacock and Balle's¹⁷ patient, a man. The period of greatest incidence is between the ages of 45 and 60 years. The frequency is the same in the two sexes.

In the reported cases the clinical diagnosis was made variously as calculous pyonephrosis with perinephritis, calculous pyonephrosis, tumor of the kidney and tuberculosis of the kidney. Krymholz⁹ was the first to report two cases of renal tuberculosis accompanied by lipomatosis. No case has been reported in which the diagnosis was made preoperatively.

Fig. 2 (case 2).—Nephrolithiasis, grade 3 replacement; no stain.

Fig. 3 (case 3).—Nephrolithiasis, grade 3 replacement; sudan IV.

Baader¹⁰ in 1778 first reported the condition in which ureteral calculus, pyelonephritis and fatty changes are observed at autopsy; but it was not until 1837 that Rayer¹¹ described in detail a case of renal

It is interesting to note that in the last thirty-seven cases reported, in twenty-five of which functional tests were performed, only five of the affected kidneys showed any function whatever. Thus, in 80 per cent of these twenty-five cases the kidney had been auto-nephrectomized. In twenty-one of the thirty-seven cases pyelography was attempted; in thirteen, or 62 per cent, of these twenty-one cases no pyelographic medium or only a very small amount could be injected into the pelvis.

Atrophic pyelonephritis as described by Braasch²³ and renal atrophy as described by Cumming and Schroeder²⁴ seem to be conditions essentially similar to that under consideration. Braasch reported twenty-eight cases; the patients' average age was 38, and none had nephrolithiasis. Cumming and Schroeder reported fifteen cases; the average age was 49, and 80 per cent of the patients had urinary stone. The important features of these conditions seem to be a decrease in the renal parenchyma, as a result of infection, and fibrous

REPORT OF CASES

An examination of the kidney specimens in the Museum of Pathology of the Ohio State University College of Medicine disclosed thirty-seven which showed a significant increase in the peripelvic fat. These were graded as to the degree of increase on the basis of 4, with 1 indicating the least amount of increase deemed to be abnormal and 4 indicating complete fatty replacement. The accompanying illustrations depict graphically the method of gradation. The specimens were stained with sudan IV for better demonstration of the fat, and the fat is therefore black in the illustrations.

The specimens are grouped in table 1 according to the nature of the underlying renal damage. The number of cases in each group is as follows: nephrosclerosis (hypertensive kidney) eight, pyelonephritis five, nephrolithiasis five, cloudy swelling five, tuberculosis three, chronic glomerulonephritis three, hypoplasia two, amyloidosis two, senile arteriosclerotic kidney two and

Fig. 4 (case 4).—Nephrosclerosis, grade 3 replacement; sudan IV.

Fig. 5 (case 5).—Tuberculosis, grade 3 replacement, sudan IV.

Fig. 6 (case 6).—Senile arteriosclerotic kidney, grade 3 replacement; sudan IV.

replacement, which follows. Although Cumming and Schroeder said little about deposition of fat, one of their illustrations is a beautiful example of fatty replacement. The average age in the reported cases of renal lipomatosis in which the figure is available is 46; in 76 per cent of the reported cases renal calculus was present. Most of the reporting authors have emphasized an infectious source. From these facts one might conclude that these variously described and named conditions are all different phases or manifestations of the same process. In all, destruction of renal tissue, usually by infection, is the primary factor; subsequent to this there is replacement by fat, fibrous tissue or both. In most cases of all types the condition is unilateral and of long duration, and most patients show great or complete loss of function of the involved kidney. We therefore suggest that all these conditions be classed together and described as renal atrophy with fibrous or with fatty replacement. Such a classification would greatly simplify the present complicated nomenclature.

hypernephroma two. Since the number of specimens of a given type of lesion in a museum varies widely both with the relative frequency of the lesion and with the collector's particular interests, these figures are felt to be of comparatively little importance.

In table 2 the cases are arranged according to the amount of fatty replacement present. The resulting figures are deemed to be more significant. It will be noted that the more severe grades of fatty increase occur with those conditions in which there is apt to be considerable destruction of renal parenchyma: nephrolithiasis, tuberculosis, nephrosclerosis, senile arteriosclerotic kidney, chronic glomerulonephritis, congenital hypoplasia and pyelonephritis.

The one case of grade 4 replacement and three of the cases of grade 3 replacement will be considered in some detail. The cases of grade 2 and of grade 1 replacement are included in the tables to show the rather wide variety of renal lesions which may be followed by fatty replacement and to show the comparative frequency of the milder degrees of this process. The cases of cloudy swelling and hypernephroma might at first seem to confuse the issue; however, although the specimens are good examples of these conditions

23. Braasch, W. F.: Atrophic Pyelonephritis, *J. Urol.* 7: 247-257 (April) 1922.

24. Cumming, R. E., and Schroeder, C. F.: Renal Atrophy, *J. Urol.* 27: 407-436 (April) 1937.

and are exhibited as such in the museum, the fatty replacement in each is due to some underlying destructive process, usually nephrosclerosis. It will be noted that none of these shows more than grade 1 replacement.

CASE 1.—M. G., a white woman aged 63, entered St. Francis Hospital Aug. 11, 1936, complaining of pain in the left flank of one and one-half years' duration. At the time of onset she had noticed increased frequency of urination, especially at night. Three months previous to admission she had noticed

2 cm. above the ureteral orifice. Indigo carmine appeared in three minutes in good concentration from the right kidney. No dye or urine could be obtained from the left kidney in forty-five minutes. The obstruction in the left ureter did not allow any sodium iodide to enter. Intravenous injection of neo-iopax showed a normal right kidney and a functionless left kidney. Urine from the right kidney showed 5 red blood cells, 8 white blood cells and 1 plus bacilli. Urine from the bladder showed 4 plus white blood cells, 1 plus bacilli and no acid-fast organisms. The diagnosis was functionless left kidney, with calculous pyonephrosis and perinephric abscess.

Five days after admission, with the patient under ether anesthesia, the perinephric abscess was drained (L. J. R.). Owing to the patient's poor condition on the table, nothing else was done. The wound was closed around an iodoform drain. The temperature rose from normal to 103 F. the first and second days. It was normal the third day and then rose to 104 F., where it remained until the death of the patient on the sixth day. A blood culture taken on the fourth postoperative day was negative. The leukocyte count two days after operation was 26,000, with 89 per cent polymorphonuclears.

The diagnosis at autopsy was nephrolithiasis on the left side; inflammatory destruction of the left kidney, with complete fatty replacement; chronic ureteritis on the left side, with stenosis; chronic cystitis; cholelithiasis, and toxic splenomegaly.

CASE 2.—V. R., a woman aged 49, entered University Hospital June 9, 1930, complaining of pain over the right lower quadrant and tenderness over the right lumbar area, chills and fever, and some urgency and frequency. There was no history

TABLE 1.—Underlying Renal Damage in Thirty-Seven Cases

swelling in the left flank, which steadily increased in size. Since that time she had passed blood at frequent intervals. She had lost 70 pounds (32 Kg.) in the preceding twelve months and had had night sweats during the whole period. The past history was otherwise irrelevant.

The patient was fairly well developed and had a mass over the left flank about the size of an orange, which was slightly tender and fluctuant and somewhat movable. The blood pressure was 125 systolic, 80 diastolic; the temperature ranged from normal to 99.5 F.; the pulse rate was 75, and the respiratory rate was 20. A blood count showed erythrocytes 4,330,000, hemoglobin content 80 per cent, leukocytes 7,100, polymorphonuclears 79 per cent and lymphocytes 21 per cent. A catheterized specimen of urine had a specific gravity of 1.015, 4 plus white blood cells, an occasional red blood cell and 1 plus granular casts. The Wassermann reaction was negative, the nonprotein nitrogen content 28 mg. per hundred cubic centimeters and the sedimentation rate normal. A plain roentgenogram of the abdomen disclosed a calculus in the region of the left kidney; a chest plate gave negative results. Cystoscopic examination showed chronic cystitis. The right ureter was catheterized easily. There was an obstruction in the left ureter

TABLE 2.—Amount of Fatty Replacement in Thirty-Seven Cases

of hematuria or stone. The pain over the right lower quadrant had been present for several years but had become acute in the three weeks preceding admission. The past history was otherwise irrelevant.

Physical examination showed a fairly well nourished woman with marked kyphosis and scoliosis. There was tenderness over the right renal area, and an indefinite mass was felt in the right lumbar area. The temperature ranged from normal to 103 F. daily. The pulse rate varied from 90 to 120 daily; the respiratory rate was 20. Urinalysis showed a specific

gravity of 1.020, a 2 plus reaction for albumin, 4 plus white blood cells and no red blood cells. The phenolsulfonphthalein test showed 45 per cent elimination in the first hour and 10 per cent in the second hour. The nonprotein nitrogen content was 22 mg. per hundred cubic centimeters on June 10, 40 mg. on June 16 and 20 mg. on June 27. A blood count showed erythrocytes 3,480,000, hemoglobin content 38 per cent, leukocytes 7,800 and polymorphonuclears 73 per cent. The Wassermann reaction was negative. Cystoscopic examination revealed chronic cystitis; the bladder was otherwise normal. The ureters were catheterized easily. The urine from the right ureter contained 2 plus white blood cells and from 1 to 3 red blood cells; the urine from the left ureter contained from 4 to 6 white blood cells and from 3 to 5 red blood cells. Indigo carmine injected intravenously appeared in the urine from the left kidney in six minutes in excellent concentration but did not appear in the urine from the right kidney after one hour. A roentgenogram showed a stone in the region of the right kidney. The pyelogram of the right side showed a marked filling defect in the pelvis. The diagnosis was renal stone on the right side and pyonephrosis.

Ten days after admission the right kidney was drained and stones were removed by Dr. W. N. Taylor. Three days later

The patient was operated on under spinal anesthesia by Dr. Taylor. A curved right lumbar incision was made into the fatty capsule. The renal mass was very large and difficult to enucleate, owing to well organized adhesions. By removing the stone from the kidney and draining the pyonephrosis the size of the kidney was reduced and its removal was made easier. The pedicle vessels were tied individually, and the wound was closed in three layers around a gauze drain. The convalescence was uneventful, and the patient was discharged July 11.

The removed kidney was large; the pelvis was dilated and contained several stones. There was marked destruction of renal parenchyma, with replacement by fat.

CASE 4.—G. M., a man aged 38, entered St. Francis Hospital Jan. 23, 1934, complaining of hemorrhage from the nose, shortness of breath and swollen ankles. He had nocturia, urinating from four to five times. His past history was irrelevant except for smallpox in 1928 and an injury to the left eye in 1932.

Physical examination showed a fairly well developed white man sitting upright in bed and evidently dyspneic. The head and the right eye were normal. The left eye showed fibrotic changes in the cornea; the left nostril contained a pledget of cotton saturated with blood. The teeth were carious. The heart was enlarged to the left, and the sounds were muffled.

Fig. 7 (case 7).—Chronic glomerulonephritis, grade 1 replacement; sudan IV.

Fig. 8 (case 24).—Nephrosclerosis, grade 1 replacement; sudan IV.

Fig. 9 (case 30).—Amyloid disease, grade 2 replacement; sudan IV.

Fig. 10 (case 32).—Hypoplasia, grade 2 replacement; sudan IV.

the temperature fell to normal. Five days later a nephrectomy was performed by Dr. Taylor. The convalescence was uneventful and the patient was discharged July 17, 1930.

The removed kidney showed calculous pyonephrosis and practically complete gross and microscopic destruction of renal tissue, with replacement by fat and fibrous tissue.

CASE 3.—N. G., a woman aged 66, entered University Hospital June 8, 1931, complaining of pain in the right side, which had been present for twenty-three years, and hematuria, which had commenced six weeks previous to admission. She had had some frequency but gave no history of gravel, chills or fever. She had lost 50 pounds (23 Kg.).

Physical examination gave essentially negative results except that it showed a mass in the right upper quadrant, which extended from the costal margin to the level of the umbilicus and to the midline. This moved on respiration and was firm and slightly nodular. Cystoscopic examination disclosed chronic cystitis. The right ureteral orifice was edematous and injected. The bladder was otherwise normal. Indigo carmine appeared from the left ureter in five minutes in excellent concentration. No dye appeared from the right side in half an hour. Urine from the right kidney showed pus 3 plus; the urine from the left kidney was normal. The urine from the bladder showed from 50 to 60 leukocytes and 2 plus bacteria. The pyelogram of the right side showed a staghorn calculus with infection. A blood count showed red cells 2,750,000, hemoglobin content 48 per cent, leukocytes 24,950 and polymorphonuclears 91 per cent. The Wassermann reaction was negative. The diagnosis was calculus of the right kidney with pyonephrosis.

The blood pressure was 220 systolic, 115 diastolic. The scrotum and legs were edematous. The urine showed a 4 plus reaction for albumin, an occasional white cell, an occasional granular cast, an alkaline reaction and a specific gravity of 1.013. A blood count showed red cells 2,250,000, hemoglobin content 40 per cent, white cells 7,750, polymorphonuclears 95, lymphocytes 4 and monocytes 1. The nonprotein nitrogen content was 60 mg. per hundred cubic centimeters. The Wassermann reaction was 4 plus. On February 12 the nonprotein nitrogen was 133 mg. The patient's condition grew steadily worse; purpuric spots developed on the neck and chest. He died March 28. The diagnosis was hypertensive cardiac decompensation, pneumonia of the lower lobe of the right lung and chronic glomerulonephritis.

The postmortem diagnosis was generalized arteriolar sclerosis, marked nephrosclerosis with fatty replacement of renal parenchyma, cardiac hypertrophy and lobar pneumonia.

COMMENT

In the seventy cases reported to date of replacement lipomatosis of the kidney a correct preoperative diagnosis has not been made. In most of these cases the diagnosis has been calculous pyonephrosis, tumor of the kidney, tuberculosis of the kidney or chronic glomerulonephritis. In each there was a history of infection over a long period.

There are no outstanding clinical symptoms to indicate the presence of replacement lipomatosis. There

may or may not be pain over the area of the kidney. The chronicity of the infection may produce pyuria with or without dysuria. The urine may be normal, because many affected kidneys are functionless and are accompanied by a normal kidney on the opposite side. The tests for blood chemistry and renal function

museum of pathology designed for teaching purposes should be ample evidence that the process, especially in its milder forms, is not uncommon. Furthermore, every pathologist performing routine autopsies is well acquainted with the fact that an increase in peripelvic fat commonly occurs in any situation in which the amount of renal parenchyma is severely decreased.

In this series of thirty-seven cases there are included (aside from hypernephroma and cloudy swelling, which are probably not primarily concerned) eight types of underlying pathologic process: nephrolithiasis, pyelonephritis, tuberculosis, chronic glomerulonephritis, nephrosclerosis, senile arteriosclerotic kidney, amyloidosis and congenital hypoplasia. Of these, four (nephrosclerosis, senile arteriosclerotic kidney, hypoplasia and amyloidosis) are definitely of noninflammatory origin, and one (chronic glomerulonephritis) is due not to the presence of bacteria in the kidney but to toxins formed elsewhere and acting on the kidney. Only three (nephrolithiasis, pyelonephritis and tuberculosis) are characterized by local infection. Furthermore, practically all the conditions which cause extensive destruction of renal parenchyma with concomitant decrease in renal bulk are included in this list. This should serve to illustrate rather clearly the point that the cause of the condition is specific only in that it implies destruction of renal tissue and decrease in the size of the renal mass.

Fig. 11.—Fatty replacement due to pyelonephritis.

usually give normal results, because the condition is almost always unilateral. Since the advent of pyelography, in 62 per cent of the cases in which this procedure has been attempted a marked filling defect has been shown or else the ureteral obstruction has been such that little or no pyelographic medium could be injected. Tests of the renal function were performed in twenty-five cases, in 80 per cent of which the affected kidney was shown to be functionless. In 76 per cent of the reported cases a renal calculus was present.

When such conditions as chronicity of infection, renal calculus, functionless kidney and a marked filling defect in a pyelogram are found concomitantly one must suspect atrophy of the kidney with replacement lipomatosis. It is to be understood that these statements apply only to the condition generally termed replacement lipomatosis and are not applicable to fatty replacement complicating the various types of Bright's disease.

COMMENT ON PATHOLOGY

Although much has been written concerning fatty replacement of the kidney, the frequency of the milder degrees of this condition, the wide variety of underlying pathologic processes and the similarity of this state to certain other rather common types of tissue change have been largely overlooked. The major purpose of this paper is to emphasize phases of the problem.

The fact that thirty-seven examples of this condition were rather easily and quickly discovered in an average

Fig. 12.—Fatty replacement due to tuberculosis.

Briefly stated, there are five types of fatty change which should be mentioned in a discussion of this subject: fatty tumor or lipoma; fatty degeneration of parenchymatous tissues, representing probably merely a change in the nature of preexisting invisible fat so that it becomes visible; fatty infiltration, consisting of storage of fat such as is seen in obesity; lipoid hista-

cytosis, which is probably a constitutional or metabolic disturbance, and fatty replacement of inactive or destroyed tissue. Of these, we are concerned mainly with the one last mentioned. Numerous examples of situations in which fat replaces regressing parenchymatous tissue can be cited, of which only a few will be

Fig. 13.—Fatty replacement due to nephrosclerosis.

given here. One of the most obvious examples is seen in the varying relationship between fat, fibrous tissue and secretory tissue in the breast under physiologic conditions; the nonlactating female breast is made up largely of fat, the lactating breast is composed almost entirely of secretory epithelium and the breast after lactation returns to its previous fatty nature. Another example is seen in the bone marrow. The marrow of infants is abundant and red; in the adult the marrow of the long bones is normally almost entirely fatty; with the advent of a condition such as pernicious anemia the marrow of the long bones again becomes active in the formation of blood cells, and the fat disappears, only to reappear in the event of satisfactory treatment. The skeletal muscle of the extremities normally contains little visible fat; however, after amputation the muscles proximal to the point of amputation undergo a disuse atrophy and are largely replaced by fat. From these few citations it will be seen that one of the normal functions of fat is to fill in any otherwise unoccupied space and to act as padding.

Summarizing these various phases of the process into a single thesis, we see that the fundamental underlying cause of fatty replacement of the kidney is a decrease in the size or bulk of the kidney from any cause; that since there are many such causes this process is common and occurs under widely differing circumstances, and that the process is in keeping with the laws of the body as a whole and is not one peculiar to the kidney.

CONCLUSIONS

1. Fatty replacement of the kidney is not a rare condition.
2. It occurs as a result of any process which destroys renal tissue or otherwise decreases the bulk of the kidney.
3. Inflammation has no specific relationship to the causation of fatty replacement.
4. This situation is similar to many others frequently occurring elsewhere in the body, in which fat replaces a regressing parenchyma.
5. Thus far a clinical diagnosis has not been made preoperatively.
6. Chronicity of infection, the presence of renal calculus, a functionless kidney and a marked filling defect in the pyelogram occurring concomitantly should lead one to consider the possibility of the presence of fatty replacement of the kidney.

Clinical Notes, Suggestions and New Instruments

OSTEOMA OF FRONTAL SINUS AND PENETRATION OF LATERAL VENTRICLE, WITH INTERMITTENT PNEUMOCEPHALUS

ELDRIDGE H. CAMPBELL, M.D., AND R. B. GOTTSCHALK, A.B.
ALBANY, N. Y.

While some osteomas of the frontal and ethmoidal sinuses may long remain asymptomatic, many others have been observed to cause local pains and headaches. If the bony growth or an associated mucocoele bulges into the cranial cavity, corresponding cerebral disturbances may follow. Pneumocephalus has been observed in several patients suffering with

Fig. 1.—Osteoma of the left frontal sinus. The head is in the lateral position, and air may be seen in the left ventricle.

these tumors.¹ In one of Dr. Cushing's cases (reported by Armitage²) the mucocoele had actually penetrated the lateral ventricle. Recently we have studied a similar case, in which

the principal complaints were of general convulsions and headaches. Since this situation is apparently uncommon, we have ventured briefly to record our observations.

A. R., a white man, aged 26, a chauffeur, was admitted to the Albany Hospital on Dec. 29, 1936, complaining of con-

and on several occasions had been accompanied by vertigo, by tinnitus in the right ear and by nausea and vomiting. They were notably aggravated by jolting and by stooping over. Shortly after the onset he commenced to hear a curious noise within his head, as of "water flowing," always from the front to the back. At times even his wife could hear this sound, particularly if he shook his head. There were long intervals when the "splashing" was not present.

Two months before he entered the hospital, violent generalized convulsions began. Since they always occurred during sleep, the patient was not aware of them, but the supra-orbital headaches were likely to be more severe the next morning. At about the same time his wife noticed some change in his personality, that he was becoming more irritable and quarrelsome.

Six weeks before he entered the hospital the headaches became particularly severe behind the left eye and in the left suboccipital region and were associated with constant nausea. The pain was worse when the patient sat up, so that he insisted on lying perfectly flat in bed, without even a pillow. A lumbar puncture then revealed clear, colorless spinal fluid, under no increase of pressure (130 mm. of water), a cell count of 2 and a total protein content of 46 mg. per hundred cubic centimeters. The Wassermann reactions of the blood and the spinal fluid were negative. A roentgenogram of the skull taken at that time by Dr. W. P. Howard disclosed a large osteoma of the left frontal sinus. The tumor appeared to extend posteriorly for from 3 to 4 cm. and to have over it the displaced and thickened posterior wall of the sinus. A subsequent review of these films revealed no air within the cranial cavity.

On examination at this time the patient was seen to be well developed, of good color, a little underweight and evidently in some distress. The pain was then principally behind the left eye, and he stated that he had been hearing the noise in his head recently. With the room perfectly quiet, a faint splashing sound could be heard distinctly when his head was quickly nodded. With the stethoscope this sound was most plainly audible in each temporal region.

The vital signs were normal, and the neck was not stiff. No external bony deformity of the skull was found. The left eye slit was perhaps a trifle narrower than the right; other than this, the general physical and neurologic examination revealed no abnormalities. The left eyeball was not protruded or rotated.

Roentgenograms made at this time with the head in the lateral position (fig. 1) revealed air in the lateral ventricles; when the head was rotated so that the forehead was up, the air was shown to have left the ventricles and to have collected outside the left frontal lobe and just above the osteoma (fig. 2).

A frontal osteoplastic craniotomy on the left side was performed (E. H. C.) on December 30, the anteriormost edge of the bone flap passing just above the frontal sinus. When the dura was retracted, the large osteoma was readily brought into view. At its upper margin there was a cone-shaped elevation surrounded by a collar of dura. When we attempted to obtain further exposure at this point, the dura suddenly separated from the osteoma, carrying within it most of a mucocele. The intracranial surface of the bony tumor was then completely exposed. It proved to have a broad attachment to the floor and the anterior wall of the sinus. Removal was accomplished piecemeal with chisel and gouge (fig. 3). The lateral portion of the sinus was filled with mucocele, which was carefully cleaned out. There was no sign of infection.

Fig. 2.—Appearance a few moments after that shown in figure 1, with the forehead rotated upward, showing the air to have passed out of the ventricle and to have collected in the subdural space.

vulsive attacks, of generalized headaches and of a noise "like water running" in his head. (He was referred to the medical service of Dr. Thomas Ordway by Dr. John Mosher of Coeymans, N. Y.) He had been in good health until fourteen

Fig. 3.—The osteoma after its piecemeal removal. The rulings are in centimeters.

months previously. At that time he began to have bouts of dull, bilateral, low frontal and retro-orbital pain, which occasionally radiated to the right ear and down the right side of the neck. Of late the headaches had become more severe

Fig. 4.—The posterior surface of the mucocele after its removal from the ventricle.

A vertical incision was then made in the dura, extending upward from the circular opening for about an inch. Some air escaped. A glistening, grayish mucocele with many small lobulations was seen bulging into the underlying brain. The original dural incision was then extended to include the

ventricle (fig. 5). The septum pellucidum and the foramen of Monro were plainly seen. The cortical arachnoid appeared to be continuous with the ependymal lining of the ventricle.

The dura was then completely closed, the defect being repaired with a small patch of temporalis fascia.

The convalescence was uneventful. In the fifteen months which has elapsed since the operation, the patient has had no headaches, no convulsions and no more of the curious sounds within his head.

COMMENT

Air is not infrequently found within the cranial cavity after a fracture through the paranasal sinuses. Dandy,³ in discussing the surgical significance of pneumocephalus, pointed out the resulting danger both from infection and from increased intracranial pressure. He showed that closure of the dural defect prevented the reaccumulation of air and obviated further danger of meningitis.

The vagaries of orbito-ethmoidal osteomas have been related by Cushing.¹ His experience and subsequently that of Hoover and Horrax⁴ showed the advisability of attacking these growths through an intracranial approach. The inward intrusion of the mucocele is seldom demonstrable by ordinary roentgenograms. Even in the absence of pneumocephalus or of neurologic signs and symptoms, it is not possible to be sure that an osteoma which involves the inner wall of the sinus has no intracranial component. Removal of the mass through the sinus may be difficult or even impossible, and the danger of carrying infection in is certainly great. In order, therefore, to deal adequately with the growth and its associated mucocele, if present, and in order securely to patch the dural opening, should one be found to exist, an osteoplastic craniotomy is essential. The incision may be placed entirely within the hairline, and no scar or deformity need result. The operation should carry with it a minimum of risk.

FRACTURE OF THE OPTIC CANAL CAUSING
OPTIC ATROPHY

EUGENE FREEDMAN, M.D., CLEVELAND

Roentgenologic visualization of the optic canal was first described in 1917 by de Kleyn and Stenvers.¹ The authors read an article by Rhese² demonstrating the visualization of the posterior ethmoid cells and the sphenoid sinuses on an oblique roentgenogram of the facial bones. Seeing the reproduction, de Kleyn and Stenvers realized that with slight modification Rhese's position could be utilized to demonstrate the optic canal. During the past few years roentgen technic of the optic canal has been simplified with the aid of excellent localizing devices developed by Pfeiffer³ and by Camp and Gianturco⁴ which eliminate the measurement of certain angles and various other haphazard elements of the technic.

The indications for roentgen examination of the optic canal are numerous, but the procedure is employed chiefly in primary and secondary diseases of the optic nerve in an attempt to demonstrate either diseased posterior ethmoid cells surrounding the optic canal, as the cause of a primary optic atrophy, or enlargement and destruction of the optic canal by a tumor of the optic nerve, or by an intracranial tumor growing into the orbit through the optic foramen.

The osseous canal normally affords great protection to the optic nerve, but during injuries to the head and eye, it may

Fig. 5.—Semidiagrammatic drawing to show the osteoma of the left frontal sinus and its relation to the intraventricular mucocele.

Fig. 6.—The patient twelve weeks after operation. The incision, being that employed for the removal of pituitary tumors, is largely concealed within the hairline.

collar of attached dura. When this was done, the entire tumor was readily lifted out of the frontal lobe. There were no adhesions between it and the brain, and no bleeding ensued.

On further inspection it was discovered that the hole made by the mucocele, and hence the latter itself (fig. 4), had extended directly into the anterior horn of the (left) lateral

sustain a fracture, and this may be followed by an optic atrophy. The atrophy is caused either by the pressure of the depressed wall or by an intracanalicular hematoma. Occasionally a loose fragment of bone may pierce the optic nerve, leading to the development of atrophy. The first report of fracture of the

Fig. 1.—Normal optic canal on the right side.

optic canal associated with optic atrophy was published by Goalwyn⁵ in 1926. The roentgenogram of the optic canal showed a fine fracture line extending from the sphenoidal fissure into the optic canal, and a hematoma was surmised to be the cause of the atrophy.

According to my knowledge the case to be reported is the second one in which the cause of optic atrophy was a fracture of the optic canal:

Fig. 2.—Depression of the lateral wall of the left optic canal and the tiny loose fragment of bone within the lumen of the canal.

E. H., a white man aged 46, admitted to the outpatient department of the University Hospitals Dec. 21, 1937, complained of blindness of the left eye of one year's duration. A year before the patient was thrown from an automobile onto the pavement in such a way that the running board came to rest on his head. The automobile had to be raised to free him. He received immediate treatment at another hospital.

5. Goalwyn, H. A.: The Clinical Value of Optic Canal Roentgenograms, *Arch. Ophth.* 33: 1 (Jan.) 1926.

As he regained consciousness he noted that there was no light perception in the left eye. He was told that there was a "blood clot" pressing on his eye.

Examination of the eyes on admission by Dr. Lorand V. Johnson revealed the following changes:

Examination with glasses: right eye, 6/7.5; left eye, no light perception.

Visual fields: right eye, normal; left eye, no light perception.

Right eye: pupil, tension, media and disk not remarkable. Left eye: no direct or consequential pupillary reflex and, with the right eye covered, an amaurotic nystagmus; media clear; very marked optic atrophy (probably secondary); macula and retina not remarkable.

Roentgen examination of the skull, facial bones and optic canal revealed a healed depressed fracture of the left zygoma and a wide linear fracture in the right occipital region measuring about 8 cm. in length and 3 mm. in width. The right optic foramen was round, was smooth in contour and measured about 6 mm. in diameter (fig. 1). The lateral wall of the left optic canal was depressed medially and in addition a loose fragment of bone measuring about 3 mm. in length and 1 mm. in width (fig. 2) was seen to lie within the lumen of the optic canal. It was concluded from this examination that the optic atrophy was caused partly by the pressure of the depressed wall of the lateral canal and partly by the loose fragment of bone, which had probably pierced the optic nerve.

The case is reported to call attention to the value of the special study of the optic canal in cases of trauma to the orbital region. This may be of great importance from the standpoint of a possible immediate exploration of the optic canal to free the nerve from the effects of pressure caused by a fracture of the walls.

HEREDITARY MULTIPLE TELANGIECTASIS WITH EPISTAXIS

METHOD OF TREATMENT

GEORGE HUNTER O'KANE, M.D., MED. SC.D., NEW YORK

Hereditary multiple telangiectasis with epistaxis, known also as Rendu-Osler-Weber disease, is a syndrome in which the terminal vessels, the capillaries and the venules become dilated.¹ On microscopic examination these dilated vessels are found to have a single layer of endothelial cells covered by a very thin epithelium.² As a result of this peculiar anatomic construction, these vessels readily become dilated and bleed profusely following the slightest trauma.

These lesions appear grossly as small red or purplish spots, usually occurring on the nasal mucosa of the septum and turbinates and sometimes occurring on the oral mucosa and skin as seen in this patient.² It is known that the telangiectases may occur anywhere in the skin or mucous membranes and may become manifest as hematuria, gastrointestinal bleeding, uterine bleeding or epistaxis.¹

This disease, unlike hemophilia, may be transmitted by either sex and may affect either the male or the female.² Unlike hemophilia, the bleeding and coagulation time are normal.

The diagnosis depends on three factors: (1) a history of repeated hemorrhages, (2) a history of familial occurrence and (3) the discovery of telangiectatic lesions in the mucous membranes.

LITERATURE

In reviewing the recent literature on the subject, one author suggests that telangiectases may occur in the brain or viscera causing early death.⁴ This has some bearing on this case.

From the Service of John D. Kernan, M.D., Columbia-Presbyterian Medical Center.

Read before the New York Academy of Medicine, Section of Otolaryngology, Jan. 19, 1938.

since all the patient's siblings died in infancy and may have been afflicted with this disease.

It has been noted by others that epistaxis caused by this disease has an unexplained tendency to cause hemorrhage in the spring and autumn months.⁵ It has also been observed

tries to inject directly into the vessel or to apply escharotics or coagulation directly. The type of packing that we have found most suitable for this purpose is half inch bismuth glycerin gauze packing. The packing may be removed in twenty-four hours.

It is advisable to attempt obliteration in several sittings, since the method is apt to be painful and to produce a local reaction. Moreover, one must bear in mind the possibility of idiosyncrasy to quinine.

It is interesting to note that in this case no new nevi arose at the site of previous injections. As new nevi do arise they can be destroyed before they cause epistaxis.

REPORT OF CASE

F., a man, aged 71, has had frequent nosebleeds since childhood. His father also suffered from frequent and severe epistaxis. The patient's nosebleeds became more severe at the age of 18 after a fracture of the nose. From this time until he was 43, he allowed the hemorrhages to continue until they stopped spontaneously. When he was 43 the bleeding increased in severity and frequency, so that he sought medical aid. Within a period of two years he underwent nine intra-nasal operations, including almost complete removal of the septum. The bleeding was not relieved. It recurred at frequent intervals, lasting from two to four hours.

Three years before admission to Vanderbilt Clinic, he received radium treatment at a nose and throat hospital in New York. During the treatment he suffered a severe epistaxis, which was controlled with difficulty and necessitated transfusion.

Fig. 1.—Right side of face showing numerous spider telangiectases.

that hemorrhages tend to become more frequent and severe toward middle age.² As I shall point out later, this was true of this patient.

In the world's literature there are reports of eighty-five families in which the disease has occurred, although the disease is probably more common than these figures indicate.⁶

METHODS OF TREATMENT

Methods of treatment have included the galvanocautery, diathermic coagulation, the application of escharotics such as silver nitrate, chromic acid bead and trichloroacetic acid. Radium has also been used. Radium makes the lesions friable and is apt to precipitate bleeding.² It has also been reported to have caused destruction of the cartilage of the nasal septum.² The difficulty with all these methods is that direct attack on the dilated vessels invariably produces severe hemorrhage that is difficult to control.

The method of treatment that we found successful in this case, after the methods mentioned had failed, is based on an indirect approach to the lesions. A fine pointed needle such as one uses to anesthetize the tonsillar area is introduced under the normal mucous membrane adjacent to the dilated vessel and enough 5 per cent quinine and urethane solution is injected to raise a small bleb alongside the vessel. The nose is then packed firmly over the injected area, which procedure allows the solution to diffuse into the vessel and obliterate it. In this way one avoids hemorrhage, which invariably ensues if one

Fig. 2.—Right side of face under infra-red rays, showing telangiectases deep in skin.

When first seen in Vanderbilt Clinic Feb. 28, 1934, he had his nose packed with cotton. On removal of the cotton a severe nasal hemorrhage ensued. The nose was immediately repacked with bismuth gauze, which controlled bleeding. On admission to the Presbyterian Hospital the packing was removed and large purplish dilated vessels were observed on the lateral nasal

6. Woodman, DeGraaf, and Opin, Edward: Personal communications to the author.

walls and the remains of the septum. When an attempt was made to electrocoagulate one of them, a drenching hemorrhage occurred, precluding further examination or treatment at that time. On each subsequent removal of packing, severe hemorrhage occurred. Dr. Maurice Lenz, chief of the department of radio therapy, was consulted and agreed to try radiotherapy. A 10 mg. radium tube in petrolatum gauze was placed in the right side of the nose and a 12.5 mg. tube was inserted in the left naris. This treatment did not obliterate the lesions and was abandoned at the suggestion of Dr. Lenz.

Among other consultants, he was seen by Drs. J. G. Hopkins and Beatrice Kesten of the department of dermatology and Dr. G. U. Carneal of the surgical staff. At their suggestion a 5 per cent solution of quinine and urethane was injected as described. This treatment was carried out with apparent obliteration of the larger lesions from March 7 to March 19, 1934. The patient was discharged with bleeding arrested.

During his stay in the hospital the stool gave a + + + + guaiac test; proctoscopic examination was negative. The melena, we believe, was due to swallowed blood, for when the nasal bleeding was controlled the stool gave a negative guaiac test. The bleeding time was three and one half minutes; the clotting time was three minutes. Hemoglobin at this time was 50 per cent; red blood cells numbered 3,100,000. The blood pressure was 140 systolic and 90 diastolic. The Wassermann reaction of the blood was negative.

Clinical examination showed varicosities on the face, in the nose and under the tongue. As far as could be ascertained, no other skin or mucous areas were affected.

Fig. 3.—Left side of face showing surface spider telangiectases and round nevi.

From March to June 1934 he had eleven more injections with definite diminution in the severity of the hemorrhages, with the exception of one severe epistaxis May 24. For two months after this he was free from hemorrhages. Then from August 11 to October 1 he had a series of hemorrhages which were readily controlled in the clinic. Feb. 8, 1935, he bled

again. The bleeding was not severe, however. During the following ten months he required only five injections. When seen Dec. 20, 1935, there were no lesions visible. No injection was required.

Since that time, more than two years ago, he has been almost entirely free from epistaxis. The slight bleeding that has occurred has been readily controlled with a light cotton plug.

Fig. 4.—Left side of face under infra-red rays, showing deep spider telangiectases and nevi.

During the past two years he has cut out alcohol and tobacco, and he drinks only one cup of coffee a day. It has been his impression in the past that these drugs seem to have precipitated bleeding.

SUMMARY AND CONCLUSIONS

1. Submucous injection of quinine and urethane, 5 per cent solution, presents a simple and effective means of controlling hereditary multiple telangiectasis with epistaxis, a troublesome and dangerous disease.
2. Vasodilators such as alcohol and stimulants such as coffee should be forbidden in the treatment of these patients.
3. This condition is not amenable to surgery.

Linnaeus, Physician and Botanist.—That Linnaeus was a graduate physician is not well known, yet he practiced medicine with great success, and as professor of medicine at Uppsala contributed much to medical teaching in Sweden at a time when the standards of medical education were at low ebb. In botany, he reigns supreme and is regarded by the world of science as one of the greatest naturalists of all time. He is often spoken of as the King of Flowers. . . . Carolus Linnaeus was born in southern Sweden on May 23, 1707, the first child of a country minister.—Larsson, B. Hjalmar: *Carolus Linnaeus, Physician and Botanist*, *Ann. M. Hist.* 10:197 (May) 1938.

Special Article

VITAMIN A

METHODS OF ASSAY AND SOURCES IN FOOD

HAZEL E. MUNSELL, PH.D.

WASHINGTON, D. C.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

The early recognition of the significance of vitamin A as an essential constituent of the diet of man made the quantitative as well as the qualitative identification of food sources an important problem for investigators engaged in research on nutrition. Although vitamin A was one of the first, if not the first, of the vitamins to be discovered, accurate quantitative methods of analysis have been slow of development. This can be explained by the fact that, although its chemical identity had been established with reasonable certainty, synthesis of the vitamin and its separation in crystalline form was accomplished only recently.¹ The situation has been further complicated by the necessity for adopting a device for expressing vitamin A potency, since obviously the values could not be expressed in terms of vitamin A. In some of the early studies attempts were made to find some product that might serve as a standard, but it soon became apparent that the vitamin A content of natural foods was so variable that the chances of finding a suitable substance were remote. Several "units" accordingly were suggested.

After the discovery had been made that carotene is converted into vitamin A by the animal organism, the Permanent Commission on Biological Standardization of the Health Organization of the League of Nations selected a well defined sample of carotene as the International Standard of Reference.² Although the selection of a substance of standard vitamin A potency has now been achieved, the preferred method of assay is still unsettled. In general the methods proposed are of three types: the so-called biologic methods, based on the behavior of laboratory animals; the color tests, and the more recently developed spectrographic, or absorption, methods. The biologic methods include the growth test; the ophthalmia test, based on the cure or prevention of the typical ocular condition due to a deficiency of vitamin A, and the vaginal smear test; which makes use of the irregular estrus and the appearance of cornified cells in the vaginal epithelium in vitamin A-deficient animals. The method of assay to be selected is dependent on the nature of the vitamin A activity, that is, on whether this activity is due to vitamin A itself, to provitamin A or to both, in the substance to be examined. The present discussion of methods will cover (1) the biologic methods, including the test based on the growth of rats and the vaginal smear test, (2) the color test with antimony trichloride

and (3) the spectrographic method. The "growth" method is at present the official method of the U. S. Pharmacopeia³ and it will be described first.

BIOLOGIC METHODS OF ASSAY

Early studies showed that the growth of experimental animals is proportional to the vitamin A content of the diet. It was also shown that vitamin A is concerned with the prevention and cure of a specific pathologic condition.

The Growth Method.—The assay of vitamin A by the growth method was introduced as early as 1920.⁴ As developed and applied in various laboratories, this method embodies the following essential features: Young rats reared on a diet supplying vitamin A sufficient for growth and reproduction but not sufficient to permit excess storage are restricted to a diet which contains all the nutrients needed for growth except vitamin A. They are maintained on this diet long enough to reduce their body store of vitamin A until it will no longer support growth (preliminary, or depletion, period). The animals are then housed individually, and each is fed a specified daily allotment of the test material, as a supplement to the basal diet, throughout a period of several weeks (test period). During this time they are weighed at regular intervals, and there is a final weighing at the termination of the test. The increase in weight, or the growth response of the animal, obtained by subtracting from the final weight the weight on the day the first supplemental feeding was given, may then be used as a measure of the quantity of vitamin A ingested. Comparable, or matched, lots of animals given different quantities of vitamin A-containing material show growth graded to the dose. The relation between gain in weight and vitamin A intake is not linear but may be represented by a curve. This relationship has been rather extensively studied by Coward; she has derived formulas for the curve, which she calls the curve of response.⁵

The growth method has been refined and standardized until it is possible to obtain results with it that have as high a degree of accuracy as can be expected of procedures in which animals are used as reagents. The details of the method as applied by different investigators lend themselves, however, to a variety of interpretations, since rules acceptable to the majority have not been established. Consideration must be given not only to selection of a basal diet devoid of vitamin A and adequate in all other factors but to such questions as age, weight and dietary history of the experimental animals; acceptable weight limits of animals at the end of the depletion period; criteria for determining when the animals are depleted and suitable for the test; length of test period required for reliable results; relative significance of results with males and with females; effect of feeding the supplements in multiples of the daily dose at periodic intervals rather than in single daily doses; number of test animals required in an assay group assigned a given quantity of test material

in order that the average gain in weight may be accepted as reliable; number of groups of experimental animals receiving graded doses of supplement required to establish the relation between vitamin A intake and gain in weight. Because most of these variables affect the accuracy of the results obtained, it seems advisable to consider the results reported in regard to them.

The vitamin A-free diet in most common use consists of casein extracted with a suitable fat solvent or subjected to prolonged heating⁶ to render it vitamin A-free, vitamin A-free starch, yeast to supply the water-soluble growth-promoting factors and a suitable salt mixture. Vitamin D may be supplied by irradiation of the oil, the starch or a portion of the yeast or through the daily administration of small quantities of irradiated cholesterol or ergosterol. Recently some investigators have added a vitamin A-free fat or oil carrying the growth-promoting unsaturated fatty acids.⁷ Linseed oil or corn oil may be used for this purpose.

The colony from which the experimental animals are obtained should be maintained on a diet containing enough vitamin A to support growth and reproduction but not enough to permit excess storage by the young. Otherwise the depletion period will be unduly long and the animals will be too large when depleted. The time required for depletion may be kept at a minimum by giving mother and young the vitamin A-free food during the lactation period⁸ or, if the mother's diet contains whole milk (powder), by substituting skimmed milk (powder) during some portion of the lactation period.⁹ Animals suitable for test purposes are described on the basis of weight at the time of weaning;¹⁰ or on the basis of weight at the end of the depletion period.¹¹ The best results seem to be obtained with animals weighing between 70 and 90 Gm. when depleted. Animals weighing more than 100 Gm. are generally considered unsuitable. Criteria for judging when the depletion period should be terminated cannot be given categorically but to a certain extent must be established by the investigator for the colony of animals with which he is working. The animals should show stationary or declining weight and may or may not have acquired ophthalmia. In any case, symptoms of extreme vitamin A deficiency should not be present.¹² The length of the test period used depends on the accuracy desired, the reliability increasing in general the longer the test is continued, at least up to eight weeks.¹³ Male and female test animals cannot be used interchangeably at all levels of vitamin A intake. At the low levels they show similar rates of gain, but at higher levels the males grow faster.¹⁴ Nine or ten animals in an assay group seem to be sufficient to give results that may be

considered reliable,¹⁵ although this number may vary somewhat according to the rate of gain¹⁶ and the sex of the animals, twice as many females as males being required for the same degree of reliability.¹⁷ The number of assay groups required to establish the relation between gain in weight and vitamin A intake depends on the reliability of the results from each group and the accuracy desired. Three points are naturally the least that can be used, and four or five are probably sufficient. The vitamin A supplements are generally specified in terms of the daily dose. The results seem to be the same, however, whether this is fed daily or in multiples of the daily dose at less frequent intervals.¹⁸

Interpretation of Results.—As already stated, the growth method was in use several years before the adoption of the International Standards of Reference for vitamins A, B₁, C and D. During that time several units were proposed for expressing vitamin A activity in terms of the measurements made. The one most extensively used was perhaps the Sherman, or the Sherman-Munsell, unit, sometimes called the rat-growth unit. This unit was defined as that amount (of vitamin A) which when fed daily (six times a week) just sufficed to support a rate of gain of 3 Gm. a week in a standard test animal (rat) during an experimental feeding period of from four to eight weeks.¹⁹ To obtain values in terms of this unit, it was customary to use at least three groups of comparable ("matched") test animals: one to receive a daily supplement of test material designed to support the standard rate of gain of 3 Gm. a week, one to receive a quantity of supplement somewhat less than this and the third to receive a quantity somewhat larger. At the end of the test the average gain in weight for each group was calculated, and a curve was drawn relating quantity of test food ingested to gain in weight. The quantity of test material required to support a gain in weight of 3 Gm. a week was then derived from this curve. The reciprocal of this value (expressed in grams) indicated the number of "rat growth" units of vitamin A per gram of material.

Although the rat growth unit was soon recognized as of little use for expressing absolute vitamin A values, the 3 Gm. a week rate of gain is often used as representative of the most reliable and most sensitive portion of the curve relating gain in weight of rats to vitamin intake.

Since adoption of the International Standards of Reference²⁰ for the vitamins it has been advisable to carry out biologic assays in such a way that the quantitative estimates derived from the results may be expressed in terms of international units rather than

20. A detailed discussion of the selection of the international standard is given in a Special Report of the Medical Research Council, standard is given in a Special Report of the Medical Research Council, information on the selection of a suitable solvent for the standard is included. This material, presented by Hume and Chick, has been summarized by E. V. McCollum (The Fat-Soluble Vitamins, in Luck, J. M., Annual Review of Biochemistry, Stanford University, Calif., Stanford University Press, 1936, p. 379).

in terms of "rat growth" units.²¹ Failure to give serious attention to the necessity of considering devices for making accurate comparisons with the international standards has in many instances led to the derivation of estimates that were far from the true values. Two methods of carrying out assays to obtain exact values in terms of international units have been suggested and described in detail.²²

Attempts have been made to derive a factor for converting vitamin A values expressed in Sherman or rat growth units to equivalent values expressed in international units.²² In this connection it is essential to emphasize the fact that the rat growth unit has no absolute value in terms of vitamin A and that, therefore, the derivation of a conversion factor is not a valid procedure. Any implied relationship must be considered as merely indicative. Values have appeared in the published literature from time to time, to be sure, but these have included extremes of 0.5 and 1.5 and there has been no basis for selecting one in preference to another. As a matter of fact, for some data reported one factor would probably more nearly serve the purpose, while in other cases the value at the other extreme might better be used.

The illogic of attempting to derive a single conversion factor of this sort may be illustrated by a consideration of factors suggested by results obtained during the past year²³ with positive control animals used in vitamin A assays on various products. All of these animals were given daily during a five week test period an amount of U. S. P. reference oil estimated to supply 1 international unit of vitamin A on the basis of the vitamin A value claimed for this oil. A total of sixty-five litters of animals were represented and all were drawn from the colony especially maintained for vitamin A assay work. Since in assays of this kind results with six to ten animals are generally considered sufficient to give an average that may be accepted as reliable, average gains in weight were derived for groups made up respectively of the controls taken from eight litters in order of the date of birth of the animals. The resulting average gains in weight for the eight groups established in this way were 18.0, 33.5, 30.3, 23.5, 16.4, 17.3, 31.3 and 28.3 Gm. By reference to a dose-effect curve for cod liver oil these were estimated to represent approximately the following vitamin A values in Sherman (Munsell) units: 0.9, 2.5, 2.1, 1.4, 0.8, 0.9, 2.2 and 1.9. On the basis of these results, therefore, the number of Sherman (Munsell) units equivalent to 1 international unit might be anything between 0.8 and 2.5. The use of another dose-effect curve might give slightly different values for Sherman units, of course, but the average gains in weight still stand as evidence of the

variability in the value of the "growth unit" even in tests carried out with presumably "standard" animals.

The Single-Feeding Growth Method.—The growth method as usually carried out involves the feeding of supplements at periodic intervals during several weeks and the estimation of quantitative values from the gain in weight of the animals during the test period. A somewhat modified form of this technic is the so-called single feeding method, in which a single dose of vitamin A-bearing material is given to vitamin A-depleted animals. In this case the survival of the animals is proportional to the vitamin A content of the material fed.²⁴ By measuring the area under the curve relating weight to survival days of animals fed different materials, it is possible to compare the vitamin A potency of these materials.²⁵ This method was recently successfully applied in the assay of pasture grasses.²⁶

The Vaginal Smear Method.—Female rats deprived of vitamin A show abnormal estrus and the presence of cornified cells in the vaginal epithelium.²⁷ This condition, which is one of the first and most pronounced evidences of a lack of vitamin A, clears up directly on the administration of vitamin A. Studies have been made to determine whether this phenomenon could be made the basis of a quantitative method.²⁸ Although the method developed has several distinct advantages, it does not commend itself for general adoption, because of the rather tedious procedure and the difficulty involved in interpreting the results quantitatively.²⁹

CHEMICAL AND PHYSICAL METHODS

As information was accumulated on the chemical and the physical characteristics of vitamin A, certain properties were identified that offered possibilities as bases for methods of quantitative analysis. The more extensively studied methods include the color tests, particularly the blue color reaction with antimony trichloride, and methods based on the selective absorption shown by vitamin A and vitamin A compounds. Although the reaction with antimony trichloride is no longer considered to have possibilities as the basis of a specific and dependable quantitative method, it may be used for certain routine purposes of control and therefore will be reviewed briefly. The spectrographic method of analysis holds promise of eventually becoming an accepted technic for quantitative work, although it is still largely in the investigative stage.

The color test and the spectrographic method do not apply to the determination of vitamin A activity due to the carotenoid precursor. No attempt will be made in the limited space allotted to this paper to discuss the blue reaction with antimony trichloride or the spectrographic technic as applied to the determination of the carotenoid precursors. The international unit,

21. The Permanent Commission on Biological Standardisation of the Health Organisation of the League of Nations at its 1931 conference (Report of the Conference on Vitamin Standards, London, June 17-20, 1931, Geneva, 1931, p. 68) adopted a specially prepared sample of carotene as the International Standard of Reference for vitamin A. A unit of vitamin A (international unit) was then defined as the vitamin A activity of 1 microgram of this international standard. During the interval from 1931 to 1934, when the next conference was held,² it was learned that the various forms of carotene do not possess the same vitamin A activity, β -carotene being more active than either α -carotene or γ -carotene. Accordingly, at the 1934 international conference a sample of pure β -carotene was adopted to replace the 1931 standard, which had been shown to be a mixture. The sample of β -carotene had been carefully assayed against the old standard, and from the average results from several laboratories, 0.6 microgram was accepted as equivalent to 1 microgram of the 1931 standard. The international unit of vitamin A is therefore the vitamin A activity of 0.6 microgram of pure β -carotene.

on the other hand, is defined in terms of the international standard, which is β -carotene. Thus it is not possible to interpret results from the color test or the spectrographic technic directly in terms of international units by comparison with results of concurrent tests on the international standard. It is necessary to use conversion factors giving the relation between the potency of vitamin A expressed in international units as determined by the biologic method and the constant for vitamin A of the chemical or physical property being measured. In several reports in which conversion factors are discussed, values determined by the biologic method and expressed in terms of international units are referred to as "biologic values." This expression should not be confused with the Sherman, or rat growth, unit of vitamin A, which is sometimes called the biologic unit.

The Color Test with Antimony Trichloride.—As early as 1920³⁰ it was suggested that the color reaction of cod liver oil with concentrated sulfuric acid might be related to the vitamin A content. Systematic investigations soon identified several color reagents, including arsenic trichloride,³¹ which gave a brilliant ultramarine color with cod liver oil. The evidence obtained seemed to support the conclusion that this reaction was specific for vitamin A. A number of the color reagents were investigated by Carr and Price,³² who gave particular attention to conditions necessary for the determination of quantitative relationships. Of the reagents studied, antimony trichloride in chloroform solution was the most satisfactory. The authors gave detailed directions for carrying out the test, and for this reason it is often referred to as the Carr-Price color test. As a quantitative method it has been used chiefly with liver oils, concentrates and extracts. In applying the test to the assay of oils,³³ a 20 per cent solution of the oil in chloroform is prepared at a given temperature, usually 20 C. Of this solution 0.2 cc. is placed in a glass cell having an internal measurement of 1 cm., and the cell is placed in a colorimeter or tintometer designed for matching the color against standard glasses. Two cc. of antimony trichloride reagent (antimony trichloride in dry chloroform saturated at 20 C.) is added so that the two solutions mix. The blue color develops rapidly and then fades. Readings are taken as the color develops, the point of maximum intensity being taken as the correct value. The values read are usually expressed as blue units, or Lovibond blue units.

Intensive studies of the antimony trichloride reaction with oils have shown that the color produced is not proportional to the amount of oil used, i. e., to the concentration of vitamin A.³⁴ The color reaction is not a linear function of vitamin A concentrations of oil. Furthermore, there seems to be no uniformity in the type of curve relating concentration of oil to color produced.³⁵ Results obtained with the unsaponifiable fraction, on the other hand, give a more nearly linear

relationship.³⁶ These values also check satisfactorily with values obtained by the biologic method.³⁷

Certain plant pigments, including carotene, are known to give a blue color reaction with antimony trichloride. The reaction with carotene may be differentiated from that with vitamin A by heating the solutions on a water bath at 60 C. The blue color with carotene will persist, while that with vitamin A changes to rose, violet-red or wine-red, according to the concentration of vitamin present.³⁸

The blue reaction with vitamin A is more stable at low temperatures³⁹ and may be stabilized by the addition of hydroquinone⁴⁰ or guaiacol.⁴¹ Certain other substances interfere with the reaction. A large number of these have been identified and tabulated according to the maximum quantity that may be present without masking the test.⁴²

Interpretation of Results.—The relation of the Lovibond blue unit to the Sherman unit of vitamin A has been variously given. The wide discrepancies in the following factors indicate the futility of attempting to select a conversion factor:

1 Sherman unit = 2.18 Lovibond blue units³⁵

10 Sherman units (eight week test) = 7.1 and 8.2 Lovibond blue units.⁴³

An attempt to establish a factor for interpreting results in terms of international units fares little better. The rich concentrate of vitamin A studied by Carr and Jewell⁴⁴ gave a value of 78,000 Lovibond blue units per gram and approximately 1.6×10^6 international units per gram, 1 Lovibond blue unit equals approximately 20 to 22 international units.

Other work⁴⁵ indicates a ratio of 20 to 1 for the vitamin A of a distilled oil, and for a natural oil the ratio is about 40 to 1. The crystalline vitamin A recently described by Holmes and Corbet⁴⁶ gave a blue value of 100,000 units per gram and has since been reported to contain approximately 3×10^6 international units per gram, giving a relation of 1 blue unit equals 30 international units.

Spectrographic, or Absorption, Methods.—Use of the spectroscope has recently come to the fore as an important method of analysis, especially for the identification of substances occurring in such small quantities as to defy the ordinary methods of quantitative chemical

analysis. If a substance shows selective absorption with characteristic maximums, it is a relatively simple matter to detect its presence and by determining the degree of absorption to obtain an estimate of the quantity present. This method has been applied in the case of vitamin A and vitamin A compounds with considerable success and promises to become an accepted method of analysis. For the most part the conventional types of equipment suitable for determining and measuring absorption in the visible and in the ultraviolet have been used, and the results have accordingly been referred to as spectroscopic, spectrographic or spectrophotometric measurements, according to the instrument employed.

Absorption of the Blue Antimony Trichloride-Vitamin A Compound.—The compound formed by antimony trichloride with the vitamin A of liver oils shows two absorption bands, with maximums near 606 and 572 millimicrons, respectively.⁴⁷ In the case of concentrates there may be considerable shift toward the red end of the spectrum, the maximums appearing near 617 and 583 millimicrons, although on dilution to give a vitamin A potency equivalent to that of cod liver oil the shift is not apparent.⁴⁸ It has been suggested that liver oils may contain two chromogens giving a blue color with antimony trichloride, one showing the maximum at 606 millimicrons and the other the maximum at 572 millimicrons.⁴⁹ Under suitable conditions both of these bands are present. It is possible, however, by changing the concentration or the temperature or by adding certain chemicals to alter these conditions so that either one or the other of these bands, but not both, is shown.⁵⁰ There is still some difference of opinion as to the specificity of these bands for vitamin A.⁵¹

The difference in behavior of the 617 millimicron and the 583 millimicron bands of the concentrates may be construed to indicate lack of homogeneity in vitamin A concentrates unless a satisfactory explanation of the difference is found.⁵²

Absorption of Vitamin A.—In 1925 Takahashi⁵³ described a highly active vitamin A preparation (biosterin) showing selective absorption in the ultraviolet with a maximum in the region of 320 millimicrons. Subsequent studies on oils and concentrates showed a high correlation between the vitamin A content as determined by the biologic method and absorption

in the region having a maximum at 328 millimicrons.⁵⁴ In the case of oils, however, not all of the absorption at 328 millimicrons is due to vitamin A. The extraneous absorption varies from oil to oil and in one case was shown to be as high as 40 per cent.⁵⁵ Reliable data therefore are obtained only by making the test with the unsaponifiable fraction. Although the measurement of absorption in the ultraviolet gives a good indication of vitamin A activity, there are still certain discrepancies that must be explained before the method can be generally adopted.⁵⁶

Application of the Spectrographic Method to the Quantitative Estimation of Vitamin A.—As implied in the foregoing discussion, the spectrographic method for vitamin A involves measurement of absorption in the region of the spectrum where vitamin A or vitamin A compounds show selective absorption. The measurement is usually made at or near the maximum of the particular absorption band used. This value expressed as a fraction of the value for 100 per cent vitamin A then indicates the proportion of vitamin A present. The validity of this relationship depends on whether Beer's law holds for all concentrations of vitamin A; i. e., whether the ratio of the coefficient of absorption to vitamin A concentration is a constant for all concentrations of vitamin A. In the application of the test this has been assumed to be the case.

It has become customary in work with vitamin A to determine the coefficient of absorption on the basis of a 1 per cent solution of 1 cm. depth. The values are usually expressed as $E_{1\%}^{1\text{cm.}}$, where E represents the optical constant, $\log \frac{I_0 \text{ (intensity of incident light)}}{I \text{ (intensity of emergent light)}}$. The wavelength at which the determination is made must be indicated. This value is sometimes referred to as the specific absorptive index or the extinction coefficient.

When the extinction coefficient has been determined either for direct absorption in the ultraviolet in the region from 320 to 330 millimicrons or for the antimony trichloride blue compound at either of the two maximums specific for this compound, the next problem is to convert the reading into vitamin A potency in terms of international units. To do this it is necessary to know the value for international units per gram divided by the index coefficient for 100 per cent vitamin A, which is the factor by which the coefficient of absorption must be multiplied to obtain the vitamin A potency in international units. Reference has already been made to the rich concentrate of vitamin A described by Carr and Jewell.⁴⁴ This substance was shown to have coefficients of absorption for the blue reaction of $E_{1\%}^{1\text{cm.}}$ 617 millimicrons = 5,000 and $E_{1\%}^{1\text{cm.}}$ 580 millimicrons = 2,600 and a coefficient of absorption for absorption in the ultraviolet of $E_{1\%}^{1\text{cm.}}$ 328 millimicrons = 1,600. Six ten-thousandths of a milligram contained slightly more than 1 international unit; i. e., the substance had a biologic

value between 1.6 and 2 million units per gram. On the basis of these constants the ratio

$$\frac{\text{biologic value (international units per gram)}}{E_{1\text{ cm.}}^{1\%} 328} = \frac{1.6 \text{ to } 2 \text{ million international units per gram}}{1,600}$$

would give a factor of approximately 1,250.

Other factors have been similarly determined on the basis of measurements made on rich concentrates of vitamin A. Those proposed up to 1935 are reviewed by Chick and Hume,⁵⁷ who give the accepted value for the conversion factor as 1,600. A more recent report by Hume⁵⁸ indicates that this factor is still the most satisfactory one to use.

From results of assays of fish liver oils by the biologic and spectrographic methods, Emmett and Bird⁵⁹ stated the conclusion that the ratio of

$$\frac{\text{international units per gram}}{E_{1\text{ cm.}}^{1\%} 328 \text{ millimicrons}}$$

for vitamin A is "close to 2,000." In the case of concentrates the conversion factor varied with the quantity of alkali used in saponification.

Reference has already been made to the report of Holmes and Corbet⁴⁶ on the separation of crystalline vitamin A. This substance gave a value for $E_{1\text{ cm.}}^{1\%}$ 328 millimicrons of 2,000. If the biologic value proves to be 3,000,000 international units, as tentatively reported, the conversion factor would be nearer 1,500 than 1,600.

The validity of the choice of the factor 1,600 or, for that matter, of any fixed factor for converting spectrographic readings to international units has been discussed by Wilkie.⁶⁰

The determination by British investigators of the vitamin A in butter may be cited as an example of the application of the spectrographic method to the quantitative estimation of vitamin A.⁶¹

Special Instruments.—The type of equipment generally used in spectrophotometric work is expensive and requires, furthermore, a skilled operator to obtain accurate results. Early in 1933 Adolph Hilger, Ltd., London, placed on the market a simplified form of the spectrophotometer, called the vitameter. This instrument, which has been described by Irish,⁶² is made especially for the assay of vitamin A and is calibrated to give $E_{1\text{ cm.}}^{1\%}$ 328 millimicron values directly. A study of results obtained with the vitameter has been made by Wilkie,⁶⁰ who recommended that persons using the instrument interpret the readings by means of a dilution curve determined for the reference cod liver oil.

A modified spectrophotometer for the assay of vitamin A was recently described by McFarlan, Reddie and Merrill.⁶³ This instrument is small and compact,

is claimed to be easy to operate and to give results in a minimum of time, about one and one-half minutes being required for a reading. The readings are given directly for $\log \frac{I_0}{I}$ at 330 millimicrons, the wavelength of the monochromatic light used. A value of 1.32 for $E_{1\text{ cm.}}^{1\%}$ 330 millimicrons for the U. S. P. reference cod liver oil was obtained. On the basis of 3,000 international units per gram given for this oil, the conversion factor for changing readings to international units was derived as 2,270.

FOOD SOURCES OF VITAMIN A

The study of food sources of vitamin A claimed the attention of investigators from the very time of discovery of this vitamin. As a result, considerably more data have accumulated on the occurrence of this factor in foods than is the case with some of the other vitamins. This material has been brought together in a publication recently issued by the United States Department of Agriculture²² and will not be reviewed in detail here.

Foods are often classified from the standpoint of vitamin potency as fair, good or excellent sources, without any clear indication as to the actual meaning of these terms. In order to have uniform terminology in the Bureau of Home Economics for expressing relative significance of foods as sources of vitamins, these qualitative terms have been tentatively defined by limiting values expressed in Sherman units per hundred grams. The bases of the definitions are given here so that there may be no uncertainty as to the meaning of the text that follows. A food source containing 19 or less Sherman units of vitamin A per hundred grams was rated an insignificant source. From 20 to 99 units was considered fair; from 100 to 999 units, good; from 1,000 to 10,000 units, excellent, and over 10,000 units, outside the class of an ordinary food. The limiting value for excellent was selected on the basis of the richest food sources. The lower limit for good was then chosen so that foods in this class would supply a significant proportion of the day's requirement. These descriptive terms should not be interpreted too categorically, for it is necessary to take into account the quantity of the food usually eaten.

In considering quantitative values it is essential to remember that a single value allotted to any food must be treated as a selected representative value within the range of variation of different samples. The more the vitamin activity of foods is studied the more patent it becomes that in most cases there exists a wide variation from sample to sample even when the effective factors are controlled as far as possible.

In foods of plant origin there seems to be a direct parallel between greenness—chlorophyll content—and vitamin A activity. Although it is known that plant tissue owes its vitamin A activity to the presence of carotene, the relation, if any, between the presence of chlorophyll and the formation of carotene is not yet clear.

Thin green leaves are among the best sources of vitamin A, many of the fresh leaves assaying well over 1,000 units (Sherman) per hundred grams and some even as high as from 20,000 to 30,000 units. The parallelism between vitamin A content and greenness is made more apparent by a study of the relative vitamin A content of green and of bleached leaves from the same plant. The outer green leaves of iceberg lettuce, which are usually removed before the head is offered to the consumer, have been shown, for instance, to be from thirty to forty times as rich in vitamin A

as the inner "bleached" leaves, which make up the head. The outer green leaves of a head of young cabbage are much higher in vitamin A content than the inner white leaves.

Other types of green vegetables having a high vitamin A potency include green seeds and seed foods such as peas and green snap beans, fleshy vegetables such as green peppers, and green stems such as asparagus, broccoli stalks and green celery, although these products are not as rich as the green leaves. Here again there is loss of vitamin A value with loss in green color, since bleached celery stalks contain little, if any, of the vitamin.

In many plant products vitamin A activity may be indicated by the yellow color of the carotene. Of the vegetables the most notable examples are carrots and sweet potatoes, both of which are excellent sources. A yellow color is especially valuable in detecting fruits that contain vitamin A, such as apricots, yellow peaches and bananas. When there is a yellow and a white variety of a given species, the yellow variety invariably has a higher vitamin A value than the so-called white variety. For example, yellow peaches and yellow tomatoes are good sources, whereas the corresponding white varieties are fair or insignificant sources. A yellow color cannot be taken as an infallible guide to vitamin A activity, however, since there are yellow plant pigments other than carotene.

Seeds such as the cereal grains, nuts and legumes are, with the exception of those having considerable green and yellow color, poor sources of vitamin A. Yellow corn—corn with a yellow endosperm—is the most important vitamin A food in this group.

A red color is sometimes mentioned as a guide to vitamin A content. It is true that such foods as red tomatoes and red peppers may be good sources. In these particular cases, however, it must be recalled that these products were green before they were red. On the whole, the association of a red color with high vitamin A content is probably more fortuitous than significant and should not be taken as anything more than indicative.

Thus a green or yellow color in foods of plant origin has come to be associated with high vitamin A activity, a rich green color indicating perhaps a relatively higher value than a yellow color.

Of the foods of animal origin, eggs, whole milk and milk products are the important sources, eggs having a rating of excellent, whole milk good and milk products of good or excellent, according to the proportion of milk fat they contain. Milk, however, since it is consumed in fairly large quantities, may be a more important source than its rating on the basis of units of vitamin A per hundred grams would imply.

Normally the cow derives her vitamin A entirely from plant material and the hen largely from the same source. Both carotene and vitamin A are secreted in milk and eggs, although the proportion of carotene to vitamin A is usually small.

The animal body does not seem to be capable of synthesizing vitamin A or the precursor carotene but must depend on its food for the needed supply. It is only reasonable to expect, therefore, that the vitamin A activity of such products as milk and eggs would vary according to the quantity of vitamin A in the diet of the respective species. There is ample evidence indicating that these products may vary between wide limits. This variability is not as great, however, as might be the case if the body were not capable of storing large

quantities of vitamin A which may be released gradually during periods of low vitamin A intake, such as the period of winter feeding. That there is a gradually diminishing output of vitamin A during such periods rather than a sharp drop has been shown by the studies made by Fraps and his co-workers.⁶⁴ On the other hand, when the intake is increased there is a sharp rise in output unless the body store has been unduly depleted.

The total quantity of vitamin A put into the egg or the milk is small compared with the total quantity ingested by the respective species. There also seems to be a maximum value beyond which the vitamin A potency of milk, at least, cannot be raised.⁶⁵ Under similar feeding conditions the butter fat from different breeds of cows shows the same vitamin A activity, although the ratio of carotene to vitamin A may vary from breed to breed.⁶⁶

The relation between the color of the egg and the vitamin A content is often questioned, color referring to the yolk and not to the shell, since the latter is a breed characteristic and has nothing to do with nutritive value. In eggs available on the market at present, the color of the yolk is of little value as a basis for the judging of vitamin A potency. If the hen has derived her vitamin A supply from green feed or yellow corn, the yolks of the eggs will be deep yellow and rich in vitamin A. On the other hand, if the diet of the hen has contained cod liver oil and the hen has not had access to green or other pigmented food, the egg yolks may be light in color though rich in vitamin A.

Variability in the vitamin A content of milk and eggs from the standpoint of food value is perhaps not as serious a problem now as it might have been, since under present day feeding practices there is not such a wide seasonal variation in the vitamin A content of the diet of dairy cows and of poultry as existed formerly. Liver might also be included in a categorical list of foods rich in vitamin A, since it is one of the richest food sources. As Sherman⁶⁷ has pointed out, however, this product can hardly be considered an important source since its production is conditioned by the demand for other meat and therefore could not be increased to supply the quantity needed to make it a regular constituent of the diet.

A consideration of the importance of various untreated foods is a small part of the story of the food sources of any vitamin. A natural food may be a perfectly good source of a vitamin and yet before it comes to the table be subjected to such treatment that little or none of this factor is left. Vitamin A is less likely, perhaps, to be lost or inactivated during procedures of manufacture and preparation at home than some of the other vitamins, since it is fairly stable to heat and not appreciably soluble in water. It is destroyed, however, by oxidation, and foods that are heated for long periods show appreciable loss of vitamin

A potency. It is not affected at the temperature of boiling water, so that foods cooked by boiling retain their vitamin A potency well. Canned foods have practically the same vitamin A value as the corresponding fresh foods. Canned products that have been stored for as long as from nine months to a year and in some cases for even longer periods still retain a large portion of their vitamin A potency.

The storing of foods in the frozen state offers one of the best methods of retaining the maximum vitamin value. The vitamin A value of frozen foods is for all practical purposes the same as that of the fresh products; provided, of course, that this statement is construed to apply to the frozen product or the defrosted product immediately after defrosting, since there may be a rapid loss of vitamin A value if the defrosted food is allowed to stand.

Dried, or dehydrated, foods show considerable loss in vitamin A content due, undoubtedly, to oxidation of the vitamin during the drying process. Dried products may show a further loss during storage.

Most foods in their natural state that are susceptible of storage for any length of time may be stored as long as from nine months to a year without serious loss of vitamin A value, and any loss taking place is very gradual.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

H. A. CASTLE, Secretary.

HANOVIA ULTRA SHORT WAVE GENERATOR MODEL #2700 ACCEPTABLE

Manufacturer: Hanovia Chemical & Mfg. Co., Chestnut Street and N. J. R. R. Avenue, Newark, N. J.

This Hanovia Short Wave Heat Generator, Model #2700, is designed for medical and minor surgical procedures. Standard equipment with this semiportable unit includes cuff and induction coil electrodes and various surgical accessories. Sufficient current is provided, according to the firm, for the electrosurgical procedures requiring cutting, coagulating and desiccating currents. When packed for shipping, the unit weighs 145 pounds.

The machine has a two-tube circuit with a fixed wavelength of about 14 meters. The patient circuit is inductively coupled.

Two variable air-spaced condensers, one in each patient's terminal, are used for tuning this circuit. One control tunes the two branches of the patient's circuit simultaneously. The unit is so arranged that the operating voltages to the filament, plate and grid of the oscillating tubes can be adjusted to line voltage variations between 100 and 140 volts.

A serial switching arrangement is provided for the filament and plate circuits of the tubes.

Fig. 1.—Hanovia ultra short wave generator, model 2700.

The current is consequently first applied to the filament and then the plate permitting the use of a foot-switch in the plate circuit only, which is preferable for surgical uses. To reduce radio interference to a minimum, a choke is used in series with the primary side of the transformer.

The input, when operating at fullload, is approximately 700 watts. The output is approximately 350 watts as measured by means of a 110 volt incandescent lamp load, galvanometer and photronic light sensitive cell.

A voltmeter is provided on the panel to permit the operator to correct any fluctuations in line voltage, so that the electronic emission from the tubes can be kept constant under all operating conditions. A milliammeter is provided in the plate circuit of the tubes to indicate when resonance is obtained in the patient circuit. The oscillating circuits are so coupled that the maximum plate current reading corresponds to direct resonance. The electrical characteristics are designed according to the firm that it is impossible to overload the machine when using cuff or bare metal electrodes.

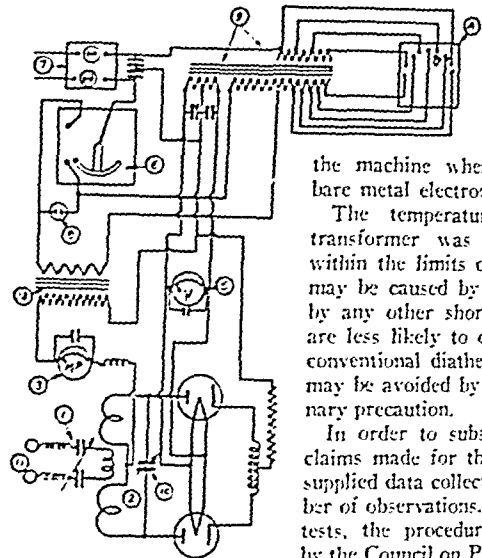

Fig. 2.—Schematic diagram of circuit.

the machine when using cuff or bare metal electrodes.

The temperature rise of the transformer was found to come within the limits of safety. Burns may be caused by this machine as by any other short wave unit but are less likely to occur than when conventional diathermy is used and may be avoided by the use of ordinary precaution.

In order to substantiate heating claims made for this unit the firm supplied data collected from a number of observations. In making the tests, the procedure recommended by the Council on Physical Therapy was followed. A cannula was introduced at the midpoint of the thigh and inserted for a distance of

two inches or until the bone was encountered. Temperature readings were made by means of thermocouples inserted into the cannula and constructed of constantan and copper placed in hypodermic needles. The constant junction was kept at 0 C. by means of a vacuum bottle and crushed ice. The couples were calibrated against a mercury thermometer certified and calibrated by the National Bureau of Standards. Potential differences were read from a Leeds and Northrup portable potentiometer of requisite sensitivity. The accuracy was believed to be within one tenth of a degree.

Six experiments were run with the cuff technic, either 3½ by 16 inches or 3½ by 21 inches. These were placed from 7 to 9 inches apart, center to center. They were spaced with felt varying from five-eighths to seven-eighths inches in thickness. The temperature averages are given here.

In using the coil technic, four turns were placed about the thigh, the outer turns in contact, the inner turns 3 inches apart.

Averages of Six Observations, Cuff Technic

Deep Muscle		Oral	
Initial	Final	Initial	Final
99.3	105.2	98.4	98.7

Averages of Six Observations, Coil Technic

Deep Muscle		Oral	
Initial	Final	Initial	Final
98.5	106.1	98.2	98.6

One layer of Zonas oiled silk was placed over the skin. Wooden air-spacers were used. The area treated was approximately 8 inches from top to bottom. In four of the tests the oiled silk was replaced by felt spacing, five-eighths inch thick.

The unit was tried out clinically by an investigator acceptable to the Council and rendered satisfactory service when used in conditions amenable to heat therapy.

In view of the foregoing report, the Council on Physical Therapy voted to accept the Hanovia Ultra Short Wave Generator, Model #2700, for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION

PAUL NICHOLAS LEECH, Secretary.

THIAMIN CHLORIDE.—Crystalline vitamin B₁ hydrochloride. — 3'-(methyl-4-aminohydrochloride-pyrimidyl-5-methyl)-N-4'-methyl-5'-beta-hydroxyethyl-3'-chlorothiazole. — $C_{12}H_{17}ClN_4OS.HCl$.

Thiamin chloride may be prepared from natural sources such as yeast or rice polishings and also synthetically.

Actions and Uses.—See general article vitamin B₁ (thiamin chloride), Allowable Claims, New and Nonofficial Remedies, 1938, page 471.

Dosage.—Dosage statements should be based on the minimum daily vitamin B₁ requirement of from 50 to 75 international units for infants and from 200 to 300 international units for adults.

Thiamin chloride occurs as white, nearly odorless crystals. On exposure to air, the crystals absorb water. It is very soluble in water, slightly soluble in alcohol. The aqueous solution (1:20) is acid to litmus (pH about 3.5). The absorption spectrum of thiamin chloride has two maximums, 233 millimicrons, 267 millimicrons and two minimums, 215 millimicrons, 250 millimicrons. Thiamin chloride decomposes on melting at 248-250 C. (micromelting point apparatus, rate of heating 5 degrees per minute). A solution of thiamin chloride in distilled water responds to the tests for chloride, U. S. P. XI, page 449.

Dissolve approximately 0.1 mg. of thiamin chloride crystals in 0.05 cc. of distilled water, or take 0.05 cc. of thiamin chloride solution (1 per cent) and add 0.05 cc. of 1 per cent solution of Reinecke Salt; immediately starlike, white crystals will appear.

Moisten 0.01 Gm. of thiamin chloride, accurately weighed, with 2 drops of sulfuric acid and ignite: no weighable residue remains. Test for heavy metals is negative (U. S. P. XI method). To 0.1 cc. of a 5 per cent aqueous solution of thiamin chloride, add 1 cc. of sodium hydroxide solution and heat gently: the escaping vapors do not turn moistened red litmus blue (ammonium salts). To a solution of 0.01 Gm. of thiamin chloride in 2 cc. of distilled water, add 0.1 cc. of diluted hydrochloric acid and 0.1 cc. of barium chloride solution: no turbidity should develop in five minutes (sulfate).

Dry 0.1 Gm. of thiamin chloride at 80 C. under reduced pressure (1 mm. mercury) to constant weight over phosphorus pentoxide (approximately ten hours): the loss in weight is not over 5.0 per cent. Dissolve about 0.02 Gm. of thiamin chloride, previously dried to constant weight and accurately weighed, in 2 cc. of water. Add 1 drop of phenolphthalein indicator solution and titrate with one-hundredth normal sodium hydroxide to a pink color: not less than 2.8 cc. nor more than 3.0 cc. of one-hundredth normal sodium hydroxide is consumed per 0.010 Gm. of thiamin chloride. Weigh out, accurately, about 0.05 Gm. of thiamin chloride, previously dried to constant weight, and determine the nitrogen by a modification of the micro Kjeldahl-Gunning-Arnold method, using selenium instead of mercury (Pregl-Quantitative Organic Microanalysis, second edition, P. Blakiston's Son & Co., 1930, p. 111). The nitrogen content is not less than 16.1 per cent nor more than 16.8 per cent. To about 15 mg. of thiamin chloride, previously dried to constant weight and accurately weighed, add 0.1 Gm. of potassium permanganate, 3 cc. of distilled water and 0.05 Gm. of sodium hydroxide. Heat the mixture for thirty minutes using a reflux condenser. Add sufficient hydrochloric acid, U. S. P. (not over 5 cc.), and heat until the solution is clear. Follow the Pregl method (Pregl-Quantitative Organic Microanalysis, second edition, p. 144) for finishing the determination of sulfur in the platinum-Neubauer micro crucible. The sulfur content is not below 9.20 per cent and not above 9.8 per cent.

For assaying tablets or ampule solution, dissolve the material in a measured amount of water and dilute so that the solution contains between 1 microgram and 5 micrograms of thiamin chloride in 1 cc. Transfer 0.2 cc. of the solution to a 25 cc. graduate cylinder and add 0.05 cc. of 1 per cent potassium ferricyanide solution and 3 cc. of 10 per cent sodium hydroxide solution. Shake the mixture and then let it stand for one hour, add 12 cc. of isobutyl alcohol and shake the mixture vigorously for two minutes. Let the mixture settle; filter 10 cc. into a 10 cc. graduate cylinder. Withdraw 4 cc. in a 25 mm. test tube and compare the solution under filtered ultraviolet light with standards of thiamin chloride. These standards are prepared by accurately weighing out previously dried thiamin chloride and diluting it until 1 cc. may contain from 0.1 to 5 micrograms per cubic centimeter. Transfer 0.2 cc. of these solutions to a suitable nonfluorescent test tube. Oxidize with potassium ferricyanide in alkaline solution, extract with isobutyl alcohol and compare 4 cc. of these standards with the unknown. The amount of the unknown solution is then calculated from the thiamin chloride standard solution matching the unknown. The potency of the tablets is also controlled by biologic assays.

Vitamin B₁ Hydrochloride (Thiamin Chloride)-Merck.

—A brand of thiamin chloride-N. N. R.

Manufactured by Merck & Co., Inc., Rahway, N. J., under license from Research Corporation, New York. U. S. patents applied for.

McKESSON'S HALIBUT LIVER OIL PLAIN, 11 cc. (See New and Nonofficial Remedies, 1938, p. 496).

The following dosage form has been accepted:

McKesson's Cod and Halibut Liver Oil.—A blend of cod and halibut liver oils, adjusted to have the potency per gram of 2,100 U. S. P. units vitamin A and 210 U. S. P. units of vitamin D.

NUPERCAINE-CIBA (See New and Nonofficial Remedies, 1938, p. 69).

The following dosage forms have been accepted:

Ampules Solution of Nupercaine-Ciba, 1:1,500 in 0.5% solution of sodium chloride, 20 cc.

Ampules Solution of Nupercaine-Ciba, 1:1,000, with epinephrine, 1:100,000, 2 cc.

Ampules Solution of Nupercaine-Ciba, 1:1,000, with epinephrine, 1:100,000, 5 cc.

METYCAINE (See New and Nonofficial Remedies, 1938, p. 67).

The following dosage forms have been accepted:

Ampules Solution Metycaine 10%, 2 cc.: Each 2 cc. contains metycaine 0.2 Gm. (3 grains) in distilled water. To be used for spinal anesthesia.

Ampules Solution Metycaine 20%, 5 cc.: Each 5 cc. contains metycaine 1 Gm. (15½ grains) in distilled water. To be used for infiltration and regional anesthesia. The solution must be diluted before using.

NICOTINIC ACID AMIDE.—3:Pyridine Carboxylic Acid Amide.—The amide of nicotinic acid, C_6H_5ON .

Actions, Uses and Dosage.—Undetermined; the product is accepted for standardization and clinical experimentation only.

Nicotinic Acid Amide (3:Pyridine Carboxylic Acid Amide) SMACO.—A brand of nicotinic acid amide-N. N. R.

Manufactured by the S. M. A. Corporation, Cleveland. No U. S. patent or trademark.

Nicotinic acid amide occurs as fluffy, needle-like, white, odorless crystals with a slight bitter taste. The melting point is 133 C., when recrystallized from acetone. It is soluble in water, alcohol and hot benzene; only slightly soluble in ether.

Dissolve approximately 0.05 Gm. nicotinic acid amide in 5 cc. of hot water, add 0.05 Gm. of flavianic acid. Evaporate carefully to dryness and take up with 5 cc. of cold water. Centrifuge and wash the precipitate three times with 2.5 cc. portions of cold water. Recrystallize from 5 cc. of hot alcohol. Centrifuge and wash the crystals twice with 3 cc. portions of ether. Filter and dry the crystals: The melting point is found to be 269-270 C. (microscopic heating stage-heating time 30 degrees in one minute), $\alpha = 1.58$, $\beta = 1.70$, $\gamma = 1.8$.

Transfer 0.1 Gm. to a vessel and dry for five hours, at a reduced pressure 2 mm. of mercury in an Abderhalden dryer at 80 C. over phosphorus pentoxide: moisture content should not be more than 0.1 per cent. Incinerate 0.05 Gm. of nicotinic acid amide: no weighable residue remains. The test for halogens U. S. P. XI is negative. Weigh out, accurately, 5 mg. of nicotinic acid amide. Determine the nitrogen content after Pregl micro Dumas method: the nitrogen content should not be more than 23.2 per cent nor less than 22.6 per cent.

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

FRANKLIN C. BING, Secretary.

GOLDEN WEST BRAND OLEOMARGARINE NOT ELIGIBLE FOR THE LIST OF ACCEPTED FOODS

The Cudahy Packing Company of Chicago presented its Golden West Brand of Margarine for consideration. The firm informed the Council that the product is manufactured in Los Angeles and that it is made from partially hydrogenated cottonseed oil, pasteurized cultured skimmed milk and salt (contains 0.1 per cent of sodium benzoate). The Council gave consideration to the evidence presented regarding the nature of the product and was of the opinion that, if the Rules and Regulations relative to labeling and advertising were met, the product would be acceptable. The package label for this brand of margarine bore a representation of tropical trees. It was the opinion of the Council that, in view of the fact that no descriptive statement of the product appeared on the label; the representation of the "palm" trees gave one the impression that the product was made from palm oil or coconut oil. Cottonseed oil is used in making the product and therefore this brand of margarine cannot be considered as a "nut" margarine. The firm was informed that it would be necessary to revise the label in such a way as to remove the Council's objection to it. This the firm was unwilling to do, stating that "the label was adopted some years ago because its design met with the approval of our advertising committee, and since its adoption it has become so well known among the trade that we are reluctant to make any alteration of it." The Council therefore has authorized publication of this statement that Golden West Brand of Margarine is not acceptable because the firm is unwilling to meet the requirements of the Council. In the opinion of the Council the product is satisfactory but the label is inappropriate.

SATURDAY, JULY 16, 1938

DANGER OF PROTAMINE INSULINS

When the slow acting insulins were first employed clinically, it was hoped they would prove less toxic than the older insulin and that the possibility of developing hypoglycemia would be practically eliminated by their use. This hope has, however, not been fulfilled; reports of reactions have appeared in considerable number. Lawrence and Archer¹ in one of the earlier discussions of protamine zinc insulin said that hypoglycemia from this type is more subtle in onset and on the whole subjective symptoms are less severe than with soluble insulin. Preliminary symptoms of shakiness, sweating and palpitation may be absent; thus severe hypoglycemic symptoms may appear without warning. Four of their patients had this type of reaction.

Further attention was called to the caution necessary in the use of protamine insulin by Jordan.² An 11 year old girl received at 9 p. m. by accident double the usual dose of protamine insulin. About 3 a. m. she was found unconscious, delirious and thrashing about in bed. Although response was prompt to intravenous dextrose, the symptoms returned later and it was two days before a normal condition could be reestablished. More recently Lindsay³ reported the case of a woman who had diabetes and cerebral arteriosclerosis. A short time following change of the insulin from the regular to the protamine type she was found comatose and she died soon thereafter. An analysis of the combined clinical and necropsy information led to the opinion that unconsciousness was due to prolonged and possibly severe hypoglycemia resulting from the cumulative effect of protamine insulin. It was concluded therefore that there is a definite possibility of danger to the arteriosclerotic patient from the prolonged and cumulative effect of the more complex insulin preparations.

2. Jordan, W. R.: Caution in the Use of Protamine Insulin, *Virginia M. Month.* 63: 730 (March) 1937.

3. Lindsay, J. W.; Rice, E. C.; Selinger, M. A., and Mish, K. H.: Protamine Insulin as a Contributing Factor in the Death of a Diabetic Patient with Cerebral Arteriosclerosis, *Ann. Int. Med.* 10: 1892 (June) 1937.

Tolstoi⁴ studied five cases of reaction to protamine zinc insulin and concluded that the hypoglycemia from protamine zinc insulin may appear from ten to twenty-four hours after its administration. Furthermore, reaction may be prolonged unless treated by epinephrine or intravenous medication. Moreover, insulin reactions of this type were often followed so rapidly by unconsciousness that little warning was available for either patient or attendants. In some of these cases, exercise appeared to be a contributing factor to the hypoglycemic reaction.

Attention has likewise been called to this modified insulin reaction by Joslin,⁵ Mosenthal⁶ and Kepler.⁷ Margolin⁸ has reported a case in which protamine insulin appeared to be at least one of the important contributing factors of death.

Ample evidence is therefore now available that protamine zinc insulin is not a fool-proof substitute for the older preparation. Although reactions to it seem to appear with less frequency, they also are often characterized by the suddenness of onset, delayed and therefore unexpected appearance, and symptoms precipitated by exercise at such a distant time as also to be wholly unexpected. Although the development of protamine zinc insulin is an advance of unquestioned value to many diabetic patients, the possibilities of delayed severe reactions cannot be ignored.

THE STANDARDIZATION OF LIVER PREPARATIONS

During the past year the U. S. P. Anti-Anemia Preparations Advisory Board has been engaged in the proper standardizing of official products. Several months ago physicians were informed that the potency of official liver products would hereafter be expressed in terms of units. The units are not interchangeable, depending on the mode of administration of the product.¹

One of the new departures of the U. S. Pharmacopeia, Eleventh Revision, is the method of controlling liver preparations. This official compendium provides that:

1. There shall have been submitted, from time to time, as requested by the Board, satisfactory clinical data from treatment with the product in question, of cases of Addisonian pernicious anemia.

2. The clinical data submitted shall satisfy the U. S. P. Anti-Anemia Preparations Advisory Board that the administration of the material in question, as prepared from liver or stomach, can produce a satisfactory result in the dose given.

1. Report on Potency of Liver Products, *J. A. M. A.* 110: 812 (March 12) 1938.

The Council on Pharmacy and Chemistry continues to accept liver products according to the criteria outlined in New and Nonofficial Remedies. In its minutes (published in *THE JOURNAL* July 9) the Council expresses the desire that the U. S. P. Anti-Anemia Preparations Advisory Board publish a statement of its standards. Since the meeting of the Council last March the Anti-Anemia Preparations Advisory Board has taken several important actions of interest to the medical profession. It has agreed that the board should publish the therapeutic and pharmacologic evidence which constitutes the basic factors for evaluating anti-anemia products. By so doing the board believes that the manufacturers will have a better idea of the meaning of the term "U. S. P. unit," and, secondly, that the standards agreed on will serve the board itself as a basis of comparison in determining the relative value of the submitted products. In taking this action, however, the board points out that such data are only a part of the criteria considered to determine the potency of a product, and the board reserves the right to use its own judgment and reach its own decisions based on all evidence presented. It is presumed by this that the board feels that the competence of the individual furnishing the data is of equal importance with the data themselves.

No sooner had the matter of expressing potency in terms of units been announced when commercial interests began either to increase the potency of their products in a competitive effort or, in case of certain nonaccepted preparations, to create units of their own. The board has decided not to grant U. S. P. recognition to injectable products of a greater potency than 15 units per cubic centimeter. As the exact composition of the active principle in liver extracts is not known chemically, the board feels that in the race to concentrate the material to a higher potency some valuable ingredients may be eliminated in the process of concentration. It is hoped that the profession will not be subjected to varying definitions for the unit of potency.

Another equally important decision is that which follows the reasoning of the Council on Pharmacy and Chemistry. The board has decided not to give consideration for acceptance or evaluation of any unofficial mixtures of antianemia products with vitamins, iron or other therapeutic agents. This is decidedly in the interest of rational medicine. When new products, such as liver and sulfanilamide, are introduced to the profession, some pharmaceutical houses immediately endeavor to complicate the therapy by presenting the physician with ready-made mixtures. If other drugs are indicated (and they frequently are not indicated), the physician should be permitted to prescribe them concurrently and in the ratio indicated for the particular patient; in other words, to use individualized medication. The board wisely points out that, without definite clinical evidence of the value of

combinations of products with liver, and with some indication that the antianemia factor may deteriorate by the addition of some of these compounds, it is desirable to avoid all these mixtures and to administer anti-anemia preparations separately.

Finally, the board has decided that it will not approve the use of the statement that the liver extract used in compounding a mixture has a certain number of U. S. P. units, because the action of the vitamin or other added product on the liver extract is not known. Only when products are tested in final form and without vitiating influence can their value be assigned.

MEDICAL EXAMINATIONS FOR DOMESTICS

Experienced physicians have occasionally encountered cases of infectious disease contracted from domestic servants. Attention was called specifically to this public health problem in the May issue of *Hygeia*.¹ Although it is feasible for prospective employers to insist on medical examination, it seems questionable that this method will have sufficiently widespread adoption to be effective. In a paper read before the International Health Officers' Conference last year, Dr. M. J. Exner² of the Health Department of Newark, N. J., described the experiences in that city with the obligatory medical examination of domestic employees in force since September 1930. By the ordinance passed at that time every domestic was required to file with the department of health a certificate from a duly licensed physician stating freedom from contagious and communicable disease. Until 1934 the examination consisted only of inspection of the skin, examination of the mouth, throat and eyes, swabs for smears only in the presence of a discharge, blood tests only with a history of typhoid or syphilis, vaccination when no scar was evident, physical examination of the chest, and x-ray or fluoroscopic examination when abnormal conditions were found. Since early in 1934 blood tests for syphilis have been made in all cases and cervical smears have been examined in all women; in men a routine inspection of the generative organs has been made and smears have been examined in event of any discharge. If the applicant was found free from infectious states, a health card was issued good for six months. If tuberculosis or syphilis was found not in the infectious state, the health cards were issued subject to being revoked if the patient failed to continue treatment.

Since June 1, 1934, the Newark Department of Health has made more than 24,000 examinations of domestics. These have shown a syphilis rate of 17.1 per cent (4.7 among white patients and 26 per cent among Negroes) and a rate of 2.4 per cent of gonorrhea. The results,

1. Kruglick, J. S.: The Real Servant Problem, *Hygeia* 16: 400 (May) 1933.

2. Exner, M. J.: The Medical Examination of Domestics, read before the International Health Officers' Conference in 1937.

however, are not an exact measure of the prevalence of syphilis because they include reexaminations; but since infectious and noninfectious persons reappear with approximately equal frequency, the prevalence rate is not widely divergent.

The argument for examinations of this nature is threefold: the protection of the family of the employer and the general public, the protection and welfare of the domestics themselves, and the general influence on disease control. Furthermore, as pointed out by Exner, the addition of large occupational groups of the general population to satisfactory syphilis control measures in the infectious stage probably serves as the best means of eradicating this controllable disease. The advantages of a comprehensive program for the examination of domestics to all groups concerned are such as to commend this activity to the serious attention of local medical societies, health departments and governmental agencies.

RENAL RICKETS

Renal rickets, renal pseudorickets, renal dwarfism and renal infantilism are terms variously employed to designate a syndrome characterized by the combination of chronic renal disease and deformity of the bones. In 1870 Steiner and Neureutter reported finding six cases of granular atrophic kidney among 256 cases of nephritis in children in which necropsies were performed. Lucas in 1882 reported five cases in which late rickets was associated with albuminuria. He considered the cases to be true rickets and suggested for them the term "rickets of adolescence." More recent investigators, particularly Fletcher and Parsons, have recognized the etiologic relationship between chronic kidney disease and deformities of the bones. In 1930 Mitchell¹ collected from the literature reports of seventy-six cases of renal rickets, to which he added two.

The symptomatology of this unusual condition is essentially that of nephrosclerosis associated with deformities of bone resembling true rickets. The sex distribution is about even. The average age of the onset is 7 years, but symptoms may manifest themselves in early infancy. In the presence of a normal mentality there is a stunted growth and failure or retardation of sex development at puberty. Among the early symptoms are anorexia, headache, vomiting, polyuria and polydipsia. Albuminuric retinitis is frequent and anemia is a constant symptom. Urinalysis shows low specific gravity, albumin, an occasional hyaline cast, and red and white cells. Kidney function tests reveal severe renal insufficiency. Increase in blood pressure is a late sign. Pigmentation of the skin described as sallow, brownish, grayish green or bronzing is a somewhat characteristic sign. Knock knees, the most constant

sign, may be the first symptom which calls attention to the underlying condition.

The changes in the kidneys in the majority of cases of renal rickets are typical of granular atrophy or chronic interstitial nephritis; other pathologic conditions such as urinary calculi have been recorded. These apparently lead to kidney dysfunction and functional insufficiency, obstruction of the urinary tract, congenital dilatation of the urinary passages, acquired or postnatal urinary obstruction and congenital cystic kidney.

The changes in the bones resemble grossly those in true infantile rickets. Enlargement of the epiphyses of the wrist and costochondral junctions, pigeon shaped chest, bossing of the frontal and parietal bones and deformities may occur. Roentgenologic and histologic studies, however, demonstrate that these alterations are somewhat different from those seen in infantile rickets; the shafts of the long bones and the flat bones have greater translucence and a more spongy appearance than are usually seen in ordinary rickets. Parsons² in roentgenologic studies of renal rickets described three well defined groups: (1) the atrophic type, (2) the florid type, which is much like that of florid rickets, and (3) the woolly, stippled or honeycombed type, which appears to be characteristic for renal rickets and quite unlike the appearance associated with true rickets.

It is assumed that the condition is a primary kidney complex resulting in faulty deposition of minerals in osseous tissues. That nephritis does occur in fetal life and in infants has been established at necropsy. Heredity and acute infections, particularly those of streptococcic nature, are among the known etiologic factors. Blood chemistry studies in renal rickets revealed a reversal of the relation between the calcium and the inorganic phosphorus content; during the acute stage, serum calcium is at its lower normal limit while the inorganic phosphorus is at its upper limit. It differs from true infantile rickets in the absence of proof that lack of minerals in the diet is concerned in the pathogenesis of the bone changes; furthermore, the antirachitic factor and ultraviolet rays do not influence renal rickets favorably. It is believed that the cause of the diminished deposition of calcium in the bone is the inability of the kidney to excrete phosphate, which leads to elevation of the blood phosphorus and depression of blood calcium. Mitchell offers the hypothesis that in renal rickets there is a shift of the excretion of the endogenous phosphates from the kidney to the intestine. He suggests that these waste phosphates will be largely in the form of sodium phosphates and ammonium phosphates, forms suited for precipitation of calcium in the intestine. The absorption of calcium will be interfered with presumably because of the formation of insoluble calcium phosphate. Blocking by the phosphorus of the absorption of calcium from the food would then lead to true calcium starvation.

1. Mitchell, A. Graeme: Nephrosclerosis in Childhood, with Special Reference to Renal Rickets, *Am. J. Dis. Child.* 40:101 (July), 345 (Aug.) 1930.

2. Parsons, L. G.: The Bone Changes Occurring in Renal and Cerebral Infantilism and Their Relationship to Rickets, *Arch. Dis. Childhood* 2:1 (Feb.) 1927.

The prognosis is bad. The patients die of uremia as a rule in the second decade. Howard³ suggests the possibility of preventing a fatal termination by the early recognition and correction of obstructive pathologic conditions in the urinary tract in some cases. He reports a case in which removal of obstruction to the neck of the bladder resulted in restoration to health.

Current Comment

WHAT IS ADEQUATE HOSPITAL SERVICE?

In the United States, for a population of a hundred and twenty million people, there are 1,124,548 hospital beds, or a ratio of 9.3 hospital beds per thousand people. Excluding mental hospitals, the figure is 4.6. Such ratios, however, when taken alone do not suffice to answer the question as to whether or not we have adequate hospital service. Much depends on whether the population is rural or urban, on the type of housing which prevails, on the availability of servants, on the habits of the people and on the degree to which they have become accustomed to the idea of hospitalization for minor illnesses. In 1937 those states which had the highest percentage of occupancy were the states which had the highest bed ratio, while the states with the smallest number of hospital beds in relation to the population had the largest percentage of unoccupied beds. This would seem to indicate that hospitals have been built where they were needed and have not been built where they are not needed. Another method of appraising the adequacy of hospital service is based on geographic distribution. On the following page of this issue of *THE JOURNAL* is a map of the United States which shows in white all those areas which are within thirty miles of a registered hospital; the remainder of the country is shown on the map in black. It is obvious that the black areas are chiefly confined to the Rocky Mountain areas and adjacent territory. In the United States 98.5 per cent of the people live within thirty miles of a hospital.

MATERNAL AGE AND MONGOLISM

In spite of the antiquity of mongolism as a medical subject, its causation has remained obscure. Bleyer⁴ has recently analyzed its incidence in relation to advanced maternal age, low fecundity among women bearing children with mongolism, prolonged interval preceding the birth of a mongoloid imbecile, maternal reproductive exhaustion, ultimogeniture and paternal reproductive exhaustion. He concluded from these studies that the role of advanced maternal age in causing mongolism is undeniable. Although the peak maternal age in the general population in this country in 1934 was 24, the peak age of mothers producing mongoloids in his series of 2,822 cases was 41. Fur-

thermore, the incidence of mongolism increases steadily through the child-bearing period. The likelihood of producing a mongoloid imbecile is increased in direct proportion to the number of menstrual cycles through which a woman has passed. Of the entire group of 2,822 mongoloid imbeciles, 900 were born to women under 31 years of age and 1,922 to women over 31. Mothers from 15 to 19 years of age produced 3.4 per cent of the mongoloid imbeciles, or only one-fourth the expectancy when judged by their proportionate contribution to the total births. In the years from 35 to 39, the mothers producing only 0.9 per cent of the births in the general population gave birth to 23.8 per cent of the mongoloid imbeciles, or an excess over expectancy of 25 to 1. The succeeding five year period, from 40 to 44, showed a further increase above expectancy of 75 to 1. No satisfactory evidence could be found of the relationship to the etiology of mongolism of the other factors investigated. Probably the apparent relation of any of these factors to mongolism can be explained simply through the admixture of advanced maternal age.

VITAMIN B DEFICIENCY AND PEDICULOSIS

Among the curiosities of current pathologic research is György's¹ recent observation that vitamin B₂ deficiency is often associated with pediculosis in rats and that avitaminotic lice-infested rats can be successfully deloused by the oral administration of riboflavin. If confirmed, this observation would seem to suggest that riboflavin is a necessary factor in the normal sensory acuity of the skin, a deficiency in this factor reducing skin sensitivity so that the rats do not keep themselves normally free from these parasites. Other explanations are, of course, possible. György's observation was a by-product of a five years study of the various types of vitamin B deficiency. Pediculosis was observed in about 20 per cent of all rats that were kept for from two to three months on a vitamin B₂-free diet. Lice, however, did not appear in control rats fed diets free from other fractions of the vitamin B complex. Therapeutic administration of riboflavin to the lice-infested rats was followed by a complete disappearance of the parasites, often accompanied by replacement of diseased patches by new fur. At first György regarded this phenomenon as purely coincidental, probably associated with a generally diminished vitality of the rats, which might then be unable to keep themselves clean in the efficient manner of normal animals. To his surprise, however, the majority of the lice-infested rats were by no means weakened or inactive. Moreover, pediculosis was not observed even in moribund rats suffering from B₆ avitaminosis or in rats moribund for lack of the maturation factor. He therefore concluded that the observed pediculosis was specific for riboflavin deficiency. Effects of B₂ avitaminosis on cutaneous reflexes and sensory acuity have not yet been studied, nor have the conceivable changes in the odor, flavor or pH of the skin as yet been investigated.

within 30 miles of a hospital; 98.5 per cent of the population of the United States lives within 30 miles of a hospital.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Alfred G. Rice, Northville, Mich., has been appointed director of tuberculosis control in North Alabama, succeeding Dr. Kellie N. Joseph, Birmingham, who retired to reenter private practice.

Society News.—At a joint meeting of the northern divisions of the Medical Association of the State of Alabama in Clarence, June 2, the speakers included Drs. Arthur B. Harris, Birmingham, on "Glioma of the Retina"; William B. Anderson, Nashville, Tenn., "Chronic Bright's Disease in Pregnancy"; Cecil D. Gaston, Birmingham, "The Enema"; James O. Morgan, Gadsden, "Uteroplacental Apoplexy" and Carl A. Grote, Huntsville, "Heart Disease and Its Treatment in General Practice."

CALIFORNIA

Plague Infection in Santa Cruz County.—According to *Public Health Reports*, plague infection was proved in fleas collected from beecheyi squirrels in Santa Cruz County as follows: A pool of six lots of fleas from ranches in the vicinity of Watsonville, which produced typical plague when inoculated into guinea pigs April 27; seventeen fleas from two beecheyi squirrels collected April 27, 8 miles east of Watsonville, and sixty fleas from one beecheyi squirrel, found dead 6 miles east of Watsonville. According to the state department of health, May 11, infection had been proved in eighteen fleas collected at the mouth of a squirrel burrow in Santa Cruz County.

Dr. Warnshuis Goes to Massachusetts.—Dr. Frederick C. Warnshuis, San Francisco, formerly secretary of the California Medical Association, has been appointed president of the American Medico-Legal Association with headquarters in Boston and editor-in-chief of its journal. The association, which was chartered in Massachusetts nine months ago under the sponsorship of some Eastern medical men, attorneys and educators, aims to coordinate all branches of the medical profession and to seek uniformity in rules and regulations dealing with medico-legal work. Its journal will be devoted to medical jurisprudence, and will be published bimonthly with eighty or more pages per issue. The first issue is expected to appear in September. Present members of the editorial board include:

Dr. George H. Magrath, emeritus professor of legal medicine, Harvard University Medical School, Boston.

Eugene O'Dunne, judge of the supreme court in Baltimore, lecturer in medical jurisprudence, Johns Hopkins University.

Dr. Tracy J. Putnam, professor of neurology, Harvard.

Dr. Myrtelle M. Canavan, curator, Warren Anatomical Museum at Harvard.

Archers Honor Dr. Saxton Pope.—The memory of Dr. Saxton T. Pope, for many years a member of the teaching faculty in the department of surgery of the University of California Medical School, San Francisco, was honored by archers of the United States July 3 when ceremonies were held the first day of the annual championship tournament of the Western Archery Association on the campus of the university at Los Angeles. Dr. Pope is credited with making archery popular in this country. According to the "History of the California Academy of Medicine," Dr. Pope's interest in the use of the bow and arrow as a sporting weapon dates from 1912 when he met Ishi, the sole survivor of the Yana tribe of Indians. He wrote "A Study of Bows and Arrows" and "The Medical History of Ishi." From 1912 until 1925 there were about seventeen expeditions made to hunt solely with the bow and arrow. In 1925, the last of the expeditions, Dr. Pope went to Africa in the company of Stewart Edward White and his companion Arthur Young. Just prior to his death, Aug. 8, 1926, from pneumonia, Dr. Pope wrote the story of the expedition in the book "The Adventurous Bowman." Born in Texas Sept. 4, 1875, Dr. Pope served as secretary of the San Francisco County Medical Society and in 1922 as president; he was director of the League for the Conservation of Public Health and secretary of the California Academy of Medicine, 1913-1914. He graduated at the University of California Medical School in 1899, becoming a member of its faculty in 1912 after carrying on a surgical practice in Watsonville.

COLORADO

Society News.—Dr. Harry H. Wear, Denver, addressed the Montrose County Medical Society May 6 on "Urologic Problems of the General Practitioner."—At a meeting of the Crowley County Medical Society May 6 Dr. William T. H. Baker, Pueblo, spoke on medical economics.—Drs. Alexander D. Waroshill and Royal C. Adkinson, Florence, discussed cholecystitis and cholelithiasis before the Fremont County Medical Society.—Drs. Samuel P. Newman Jr. and Alfred M. Wolfe, Denver, discussed "Fractures of the Elbow and Ankle" before the Northeast Colorado Medical Society at its meeting in Sterling May 12.—Dr. Alta E. C. Bordner, Pueblo, discussed marihuana before the Pueblo County Medical Society May 17.

CONNECTICUT

Personal.—Dr. Alice Hamilton, Hadlyme, received the honorary degree of doctor of science from the University of Rochester (N. Y.) at its eighty-eighth annual commencement June 20.—Dr. De C. Y. Moore, chairman of the board of health and health officer of Manchester for nearly twenty-five years, has been appointed medical examiner to succeed the late Dr. Le Verne Hoffnes.

DISTRICT OF COLUMBIA

Society News.—Dr. Winfred Overholser addressed the Academy of Medicine of Washington at its spring meeting May 14 on "The Psychiatrist in Court."—Dr. Daniel L. Borden has been elected president of the Washington Academy of Surgery and Dr. John O. Warfield Jr. secretary.

Survey of Cancer of Lungs.—The U. S. Public Health Service is conducting a survey of cancer of the lungs in Washington hospitals as a part of a national study, according to the *Washington Star* June 7. Dr. James A. Crabtree, Chattanooga, Tenn., formerly assistant head of the health and safety department of the Tennessee Valley Authority, is in charge. Similar studies will be made in hospitals throughout the country treating cancer.

ILLINOIS

New Health District.—Dr. Wilmier M. Talbert, Decatur, formerly city physician for Decatur, has been appointed health officer of a new district health unit with headquarters at Clinton. The counties of Macon, Moultrie, Dewitt, Piatt and McLean are included in the new unit.

Chicago

Graduate Course in Pediatrics and Obstetrics.—A graduate course in obstetrics and pediatrics will be conducted by the department of obstetrics and pediatrics at Research and Educational Hospital during July and August. The speakers will include Drs. Joseph L. Baer, Frederick H. Falls, Fred L. Adair, William C. Danforth, Abraham F. Lash, William H. Browne and Charles Newberger, all obstetricians, and Drs. Julius H. Hess, Clifford Grulac, Arthur H. Parmelee, Isaac A. Abt, Maurice L. Blatt, Robert A. Black and Henry E. Irish, all pediatricians. The course, consisting of lectures on special subjects, round table discussions, ward walks in the hospital, dispensary service, manikin, home and hospital delivery, is designed to meet the needs of the general practitioner as they are encountered in everyday practice. The registration fee is ten dollars; checks should be made payable to the University of Illinois, 1853 West Polk Street.

INDIANA

Survey of Industrial Hazards.—A study of industrial hazards will begin this month in Indiana, according to the state medical journal. Conducted by the new bureau of industrial hygiene, the survey is expected to provide a cross section of health conditions in the state's factories. While it will not be possible to inspect every plant, a check will be made in industries known to have hazardous health conditions.

Society News.—Dr. John W. Ferrin, Chicago, discussed prostatic surgery before the LaPorte County Medical Society in Wanatah May 19.—The Daviess-Martin County Medical Society was addressed in Washington May 31 by Dr. William N. Wishard Jr., Indianapolis, on "Prostatic Obstruction."—Dr. Emor L. Cartwright, Fort Wayne, discussed diseases of the rectum and anus before the Adams County Medical Society in Decatur May 20.—At a meeting of the Parke-Vermillion County Medical Society in Clinton May 18 Dr. James H. Hawk, Indianapolis, spoke on puerperal infection and antepartum care.—The Wayne-Union Counties Medical Society was addressed in Liberty June 9 by Dr. Franklin D. Johnston, Ann Arbor, on

"Electrocardiology in Diagnosis of Coronary Occlusion."—Dr. Frank H. Lahey, Boston, discussed "Peptic Ulcer: Its Non-surgical and Surgical Management" before the Muncie Academy of Medicine May 10.

IOWA

District Meeting.—The Iowa and Illinois Central District Medical Association held its annual meeting at the Outing Club in Davenport May 25. The speakers were Drs. Dallas B. Phemister, Chicago, on "Use of the Bone Graft in the Treatment of Bone Tumors"; Alexander E. Brown, Rochester, Minn., "Sulfanilamide Therapy," and James H. Means, Boston, "The Commoner Deficiency Syndromes Found in a Medical Clinic." Dr. Anton Knutson, Reynolds, Ill., lectured in the evening on "Hunting Big Game in Africa." Two members who have completed fifty years in practice were given special recognition at this meeting: Drs. George B. Maxwell, Davenport, and George A. Wiggins, Milan, Ill.

KANSAS

Hall of Health in Wichita.—The Sedgwick County Medical Society sponsored a "hall of health" in Wichita May 7-16. The period of the exhibit included the annual session of the Kansas Medical Society. It was formally opened with the unveiling of the Camp Transparent Woman, the ceremony being broadcast over a local radio station. There was a 10 cent admission charge; the cost was \$2,500 and a total of 27,000 persons visited the hall. The society furnished the rent, booth space, shelving and electricity free of charge. There were fifty-two exhibit spaces.

KENTUCKY

Society News.—Drs. Dougal M. Dollar and John Stites addressed the Jefferson County Medical Society, Louisville, June 6, on "Anesthesia" and "Agranulocytosis" respectively. At the meeting June 20 the speakers were Drs. Gordon S. Buttorff, "Control of Hemorrhage with Special Reference to Moccasin Snake Venom"; Ellis S. Allen, "Hazards of Blood Transfusion," and William J. Martin, "Anal Fissure."—Dr. George A. Hendon addressed the Louisville Surgical Society June 3 on "Multiple Abscess of the Liver."—Dr. Frederick G. Speidel addressed the Society of Physicians and Surgeons of Louisville June 16 on "Treatment of Nephritis."—Dr. John Walker Moore, Louisville, addressed the Louisville Medico-Chirurgical Society recently on "Studies in Hemodynamics of Patients Receiving Insulin Shock Therapy."—Drs. Franklin H. Russell, Wickliffe, and Willis R. Moss, Clinton, addressed the Tri-County Medical Society of Hickman, Carlisle and Ballard counties June 7 on angina pectoris and scarlet fever, respectively.

LOUISIANA

Past Presidents' Night.—The Orleans Parish Medical Society devoted its June 29 meeting to honoring past presidents. Dr. Shirley C. Lyons gave the address of welcome and Dr. Marcus J. Magruder the response. Dr. James M. Mason, Birmingham, Ala., gave "A Review of Progress in the Treatment of Empyema" and Dr. Rudolph Matas presented certificates to the honor guests on behalf of the society. There have been forty-eight presidents since 1878, when the society was established.

MASSACHUSETTS

Personal.—Dr. Ruth E. Fairbank, associate in psychiatry, Johns Hopkins University School of Medicine, Baltimore, has been appointed professor of hygiene at Mount Holyoke College, South Hadley, Science reports. Dr. Fairbank graduated at Johns Hopkins in 1916.

Courses for Graduates.—A course in urology will be held at the Harvard University Medical School, Boston, July 18-30, under the direction of Dr. George G. Smith and his associates. Mornings will be devoted to operations, ward visits, cystoscopic diagnosis of urologic problems, while the afternoons will be given over to special discussions. The fee is \$80. Additional information may be obtained from the assistant dean, Courses for Graduates, Harvard University Medical School, Boston.

MICHIGAN

Society News.—Dr. John J. Prendergast Jr., Detroit, has been elected president of the newly organized Michigan Society for Industrial Hygiene. —Dr. Harold L. Morris, Detroit, discussed "Pyelitis of Pregnancy" before the Muskegon County Medical Society in Muskegon June 17.

MINNESOTA

Dr. Harrington Honored.—A dinner was given for Dr. Francis E. Harrington, health commissioner of Minneapolis and founder and director of the Lymanhurst Health Center at the Minnesota Union, University of Minnesota, May 23. The occasion also commemorated the seventeenth anniversary of the health center as a school for tuberculous children. Dr. William A. O'Brien, associate professor of pathology and preventive medicine and public health, University of Minnesota Medical School, Minneapolis, was toastmaster and speakers included Drs. Arthur E. Benjamin, Stephen H. Baxter, Chester A. Stewart, Jay Arthur Myers and Irvine McQuarrie, all of Minneapolis; Robert B. J. Schoch, health officer of St. Paul, and Carl Buck, Dr.P.H., New York, field director of the American Public Health Association.

Dr. Meyerding Resigns—Receives Award.—Dr. Edward A. Meyerding, St. Paul, secretary of the Minnesota State Medical Association for fourteen years, resigned at the recent annual meeting in Duluth. Dr. Meyerding had been on a year's leave of absence from the association. He will continue on a full time basis as executive secretary of the Minnesota Public Health Association, a position he has also held since 1924. At the annual banquet of the association June 30, Dr. Meyerding was presented with the first Distinguished Service Award created by the house of delegates of the state society to be presented on occasion in recognition of special service to the association. A native of St. Paul, Dr. Meyerding graduated at the University of Minnesota Medical School, Minneapolis, in 1902. Before he became associated with the medical and public health associations, he served as director of the division of hygiene and special classes of the public schools of St. Paul for fifteen years. He is president of the Mississippi Valley Conference on Tuberculosis.

MISSOURI

Annual Fall Conference.—The sixteenth annual fall clinical conference of the Kansas City Southwest Clinical Society will be held in Kansas City, October 3-6. Guest speakers will include Drs. Grady E. Clay, Atlanta, Ga.; James B. Costen, St. Louis; Thomas Leon Howard, Denver; Chester A. Stewart, Minneapolis; William J. Dieckmann, Chicago; Frank R. Ober, Boston, Mass.; Louis J. Karnosh, Cleveland; Elmer L. Sevringhaus, Madison, Wis.; William D. Sansum, Santa Barbara, Calif.; Lawrence Reynolds, Detroit, and Isidor S. Ravdin, Philadelphia.

Cornerstone Laid for Psychopathic Institute.—The cornerstone of the new Malcolm A. Bliss Psychopathic Institute, St. Louis, was laid June 26. A city institution, the building will cost about \$1,000,000 and accommodate 185 patients, with 142 beds for white patients and forty-three for Negroes. Funds for the project came from a 1934 bond issue and a PWA grant, newspapers reported. The institute will be primarily for the study of new and borderline cases, the latter to be segregated from the actually insane. The building will be ready about March 1939. Dr. Bliss, in whose honor it is named, was for many years associated with the city institutions. He died in 1934.

NEW HAMPSHIRE

Shellfish from Bay Area Banned.—The state board of health has recently placed a ban on the sale for human food of shellfish taken from the "Great Bay area" because of contamination of rivers flowing into the area with sewage from Portsmouth, Dover and other towns. Collection and analyses of clams and water from the lower part of the area has definitely shown that shellfish taken there is unfit for food, and studies are in progress of clams from the mouth of the Exeter River and oysters from the Oyster River.

NEW JERSEY

Dr. Shope Awarded Alvarenga Prize.—The College of Physicians of Philadelphia has awarded the Alvarenga Prize for 1938 to Dr. Richard Edwin Shope of the department of animal and plant pathology of the Rockefeller Institute for Medical Research, Princeton. The award was made in recognition of his research on influenza. Dr. Shope, who is 35 years old, is a graduate of the State University of Iowa College of Medicine, Iowa City, and has been associated with the Rockefeller Institute since 1925. In 1937 he received the John Phillips Memorial Prize of the American College of Physicians. The Alvarenga Prize was established by the will of Pedro Francisco de Costa Alvarenga, an associate fellow of the College of

Physicians of Philadelphia, to be awarded annually on the anniversary of the death of the donor, July 14, to the author of the best memorial or unpublished essay on any branch of medicine deemed worthy of the prize.

NEW YORK

Committee to Aid in Survey.—A committee of the Medical Society of the State of New York has been appointed to cooperate with county medical societies concerning questionnaires in the survey of medical service now in progress under the sponsorship of the American Medical Association. Members of the committee, which was appointed by the president of the society, Dr. William A. Groat, Syracuse, are Drs. Oliver W. H. Mitchell, Syracuse, chairman; Herbert H. Bauckus, Buffalo; Frederic C. Conway, Albany; Charles Gordon Heyd, New York; Walter W. Mott, White Plains; Leo F. Schiff, Plattsburg, and Edward G. Whipple, Rochester.

New York City

Commission to Study Crippled Children.—A study of the care of physically handicapped children was launched recently with the appointment by Mayor La Guardia of a special commission with Dr. Philip D. Wilson, surgeon in chief of the Hospital for Ruptured and Crippled, as chairman. Dr. Vernon W. Lippard, associate attending pediatrician to the New York Hospital and instructor in pediatrics at Cornell University Medical College, has been selected to direct the survey, which will continue until July 1, 1939, and has obtained leave of absence from his other duties for that period. The first step will be the establishment of a registration bureau in the headquarters in the Lower West Side Health Center, 303 Ninth Avenue, Manhattan. The survey will analyze the type of care a child receives when once referred to a hospital or organization; it will also determine the extent of duplication of services and whether continued service is given to the handicapped child until he reaches maturity. The material thus gathered will be used in developing a program for proper physical, mental, educational and vocational care of these children, and the commission will have the right to recommend changes or revisions in the present set-up which may be considered necessary. Members of the commission are, in addition to Dr. Wilson, Drs. Alan De Forest Smith, Bradley L. Coley, Leo Mayer, Foster Kennedy, Herbert B. Wilcox, Howard R. Craig; Thomas S. McLane, treasurer, Association for the Aid of Crippled Children; Stanley P. Davies, director, Charity Organization Society; Lionello Perera, member, board of child welfare; Miss Katherine Faville, director, Henry Street Nursing Service, and Mrs. Adrian Van Sinderen, president, Brooklyn Visiting Nurse Association. Ex officio members are Dr. John L. Rice, city health commissioner; Dr. Sigismund S. Goldwater, hospital commissioner; Dr. Edward S. Godfrey Jr., Albany, state health commissioner; Harold G. Campbell, Ph.D., superintendent of schools, and William Hodson, welfare commissioner.

NORTH CAROLINA

Seminar on Tuberculosis.—The Buncombe County Medical Society held its second annual seminar on tuberculosis in Asheville July 11-16. Sessions were held partly in the Asheville Medical Library and partly in offices of several physicians, who gave special demonstrations and conferences. Among the speakers, all of Asheville, were Drs. Alfred Blumberg, "Pathology of Tuberculosis"; Thomas R. Hufines, "Tuberculosis of the Genito-Urinary Tract"; Paul H. Ringer, "Differential Diagnosis of Pulmonary Tuberculosis"; William P. Herbert, "Principles of Collapse Therapy," and Robert R. Ivey, "Emergency Surgery on the Tuberculous."

OHIO

Gift for Research at Ohio State.—Ohio State University College of Medicine, Columbus, has received a gift of \$200,000 from the estate of Miss Marietta Comly, formerly of Columbus and Washington, D. C. Miss Comly's gift is a memorial to her father, the late Dr. J. W. Comly, and to her brother-in-law and sister, Dr. and Mrs. Nathaniel R. Coleman, Columbus. Dr. Coleman at his death bequeathed his medical library to the university and Miss Comly contributed \$3,000 for additions to the library. Later she set up a trust fund of \$20,000 for an alcove to house the Coleman collection. In 1929 she gave \$1,000 for a student loan fund and in her will gave \$5,000 more for that purpose. According to Dr. Charles A. Doan, chairman of the department of medicine and director of medical research, the income from the gift will be used to expand research programs already in progress at the college of medicine.

SOUTH CAROLINA

Secretary Hines Honored.—At the recent annual meeting of the South Carolina Medical Association at Myrtle Beach, the association presented to Dr. Edgar A. Hines, Seneca, a silver tray, pitcher and goblets in recognition of his long service as secretary and editor of the journal of the association. The presentation was made at the president's ball by Drs. Leonidas M. Stokes, Walterboro, president, and James R. DesPortes, Fort Mill, president-elect. Dr. Hines, who graduated from the Medical College of South Carolina in 1891, has been secretary since 1909 and editor of the journal since 1912. Among many activities Dr. Hines has been vice chairman of the state board of health for many years and was one of the founders of the board's bureau of child hygiene. In 1929 he was president of the South Carolina Pediatric Society. For many years he has been a member of the House of Delegates of the American Medical Association.

TEXAS

District Meeting.—The eleventh district of the Texas State Medical Association held a meeting in Athens recently with the following speakers, among others: Drs. George R. Herrmann, Galveston, "Modern Conceptions in the Diagnosis and Treatment of Hypertensive Arteriolar Disease"; Christopher B. Carter, Dallas, "Resection of the Recurrent Laryngeal Nerve in Tuberculosis of the Larynx"; Don Price, Athens, "Acute Suppurative Otitis Media," and Howard D. Cogswell, Tyler, "Treatment of Burns."

GENERAL

Broadcast on Accidents from Fireworks.—The National Society for the Prevention of Blindness prepared an electrical transcription of a ten minute program depicting dangers to eyesight from fireworks for presentation on and near the Fourth of July. The record includes an interview with Lewis H. Carris, managing director of the society, by Myron Weiss, associate editor of *Time*, and a brief dramatic sketch of a typical fireworks accident in which a boy is injured. The society offered the transcription free of charge to radio stations that desired to use it.

Society of Allergists.—The Ohio Valley Society of Allergists was recently organized with members from Indiana, Kentucky and southern Ohio. Dr. Albert R. Zoss, Cincinnati, was elected president and Dr. John Harold King, Cincinnati, secretary, at an organization meeting in Cincinnati last February. The spring scientific meeting was held in Cincinnati May 21-22 and was devoted to a discussion of fungi. Dr. Samuel M. Feinberg, Chicago, gave an address on "The Role of Air-Borne Fungi in Allergy." Other guests included Drs. Frederick W. Wittich, Minneapolis; John M. Sheldon, Ann Arbor, and Karl D. Figley, Toledo.

Society News.—The medical section of the American Life Convention held its twenty-eighth annual meeting at Asheville, N. C., June 16-18. Dr. Albert E. Johann, Des Moines, Iowa, was elected chairman, Dr. Maurice B. Bender, New York, vice chairman, and Dr. Benjamin F. Byrd, Nashville, Tenn., secretary. Dr. Henry Chesley Bush, Livermore, Calif., was elected president of the National Tuberculosis Association at its annual meeting in Los Angeles June 21. Drs. Frederick T. Lord, Boston, and Paul P. McCain, Sanatorium, N. C., were elected vice presidents; President Roosevelt and Dr. Henry D. Chadwick, Boston, were elected honorary vice presidents. Dr. Charles J. Hatfield, Philadelphia, was reelected secretary.
